Improvement Act (IDEA). There are three main categories of individuals with physical disabilities. These include (1) neuromotor differences, (2) musculoskeletal disabilities, and (3) degenerative disorders. Children with physical disabilities often need the services of physical therapists, occupational therapists, speech-language pathologists, or other support personnel. Children with physical disabilities should receive services that are evidence based, including appropriate assessment, child-focused instruction, family-based services, and interdisciplinary or transdisciplinary teaming and collaboration. Young children with orthopedic impairments may need assistive technology and special equipment for seating and positioning as well as special devices to participate in classroom activities and feed themselves. Adapted clothing may be used for dressing needs, while other equipment may be needed for lifting, carrying, and transitional experiences. Adaptations often are necessary for mobility in home, school, and community settings. Other special considerations often are necessary for optimal early intervention and early childhood education experiences.

PHYSICAL EDUCATION

From a historical perspective, educational theorists in early childhood and physical education typically ignored the need for instruction aimed at young children's physical development. There was a general belief that the physical needs of children from birth through 4 years could be satisfied in the home setting or later when the child entered elementary school. It was not until the early 1960s in the United States, when leaders in the field of physical education began seeking new instructional content for the kindergarten through Grade 2 programs, that educators began to fully realize the young child's movement potential. Their search in Europe for age-appropriate content led them to the works of an Austro-Hungary-born movement theorist named Rudolph Laban (1879–1958). Laban's focus on analyzing basic movement skills had been acknowledged worldwide in the areas of dance, theater, mime, gymnastics, and fencing. When his theories were first introduced in the 1960s in the United States, a program was developed emphasizing four major movement concepts. These four concepts gained great attention from physical education teachers and have since served as the foundation for movement education for elementary-school-age children. Later, in the 1980s, the same four concepts became the foundation of early childhood physical education in public school settings and in many early childhood centers.

Of the four concepts, body awareness is the most frequently implemented with preschool children. Body awareness activities ask the child to identify the names and locations of various body parts and to physically explore the movement possibilities of those extremities. Participating in these activities helps young children develop a more realistic conception of their body's capabilities as they learn that particular body parts are responsible for specific large and fine motor movements. Common activities include asking the child to use different body parts to imitate the expressive feelings and actions of characters in fictional movement narratives, or to challenge the

child to use his or her imagination and perform the actions of familiar objects or things that move, or to create familiar alphabet letters or numerical numbers by bending or stretching in order to form lines and half circles with his or her body.

Body awareness activities also teach the child to demonstrate shapes that the body can make such as a twisted, bridge, tunnel, flat, wide, tall, crooked, and round shape. These shapes occur in many sport activities for adolescents and adults. However, the greatest benefit of teaching body awareness activities to young children is to expand their understanding and performance of a large variety of different movements. Many physical education teachers refer to this focus as the young child's movement vocabulary. Although the list is fairly expansive, numbering more than 60 specific movements, the most typical locomotor movements in preschool physical education lessons focus on teaching the correct mechanics of walking, running, jumping, hopping, and skipping. The most common nonlocomotor movements that benefit the child's healthy development but do not require movement throughout the instructional area include twisting, turning, swaying, bending, and stretching.

Children acquire the concept of spatial awareness as they begin to understand how much space the body requires to move successfully throughout the playing area. Age-appropriate obstacle courses enhance the child's understanding of spatial awareness when children are challenged to remain in a compact shape while moving through obstacles of different heights and widths. These obstacles include child-size tunnels, recycled car tires to balance on or move around, geometric shapes, and cardboard boxes large enough to crawl through. This activity can also offer the child different imaginary pathways or routes to follow along such as a zigzag, curved, straight, or diagonal path. Children can also move on different horizontal planes such as high, medium, or low levels, and can explore moving over different types of surfaces such as gymnastic mats and floor rugs of different textures. In spatial awareness lessons, the area within a child's immediate reach is introduced as being his or her personal space, and all areas beyond the child's arm extension are referred to as general space.

The third movement concept requires teachers to plan lessons aimed at showing the child how the body can move according to time, force, and flow. Time is the child's ability to move the whole or parts of the body quickly or slowly. This element of the concept is associated with speed such as quick or slow, sudden, or sustained movement. The next element enhances the young child's ability to utilize different degrees of muscle tension and strength for more efficient movement. Laban referred to this as effort, but the term *force* is commonly used in the United States. This element is associated with the child demonstrating heavy or light, harsh or gentle, strong or weak, and hard or soft movements. The final element, known to be critical for effective coordination and sport skills in the older grades, is called flow and challenges children to link movements sequentially. Chase and flee activities that help the child to discover how to move quickly, stop quickly, and perform a mature balance shape address the concept of flow. One example includes asking the child to stomp like a heavy elephant, jump quickly like a powerful kangaroo, gallop forcefully like a giraffe, and then freeze the body's muscles suddenly as if hiding from a make-believe lion.

The fourth movement concept, known as relationships, teaches the young child how to move in relation to other classmates by interacting with a partner, small group, or whole class. A few sample relationships include interacting with another preschool child by either following, leading, meeting, parting, passing, or simply copying and mirroring their peer's actions. Children can also use their bodies and a partner's body to show taller than, shorter than, less than, or greater than. Small group activities can be used to teach the elements of behind/in front, between, among, alongside, over/under, near/far, and along/through. This concept serves as a foundation for young children moving in the presence of others. Sample activities include exploring a variety of twisted shapes such as pretending to be a pretzel by rotating specific body parts around a classmate's body, or interacting cooperatively within a small group to explore three different ways to move like a make-believe

train, or working collectively and using other children's bodies to create large group shapes resembling a bridge, a house, a school bus, or a rocket shape.

One additional element of relationships is to utilize a variety of lightweight equipment, such as bean bags, air-inflated balls, wooden blocks, sheets of newspaper, plastic hoops, and child-size floor mats, and challenge children to position their bodies in relation to the objects according to above, below, over, under, near, far in front of, behind, to the side, around, and between objects. Sample relationship activities can also focus on manipulative skills such as keeping a balloon afloat in the air using different body parts or performing the motor skill mechanics involved with rolling, fielding, or kicking a ball.

In 1995, the premises of quality movement programs for young children were reinforced in a position statement written by experts from the National Association for Sport and Physical Education. The document was titled *Appropriate Practices in Movement Programs for Children Ages 3–5*, and it has undergone additional expansions and editions. The appropriate practices are highly circulated and the document remains a highly used resource.

Guidelines for Physical Activity

While the emphasis on movement concepts has continued in preschool physical education, the need for additional physical activity for children ages birth to 5 years had gained significant attention by the year 2000. In 2002, a step was taken by physical education's national association to create a document titled *Active Start: A Statement of Physical Activity Guidelines for Children Birth to Five Years*. These first-ever guidelines defined *physical activity* for young children as any bodily movement produced by skeletal muscles that results in energy expenditure. According to the document, the term *physical fitness* implies that a child is in a state of well-being and can meet the daily physical challenges that are appropriate to his or her stage of development. Again, movement

activities were recommended as a way to increase the child's overall body strength, bone density, and cardiovascular system.

This additional emphasis on physical activity introduced two specific types of physical activity for early childhood. The first term is *vigorous physical activity*. Vigorous physical activity is performed at an intensity so that children's breathing and heart rate are elevated. Sample activities for this age level include chase and flee games or dancing and moving about to lively music. Obviously young children do become fatigued sooner than elementary school children since their bodies are still physically developing. However, even short bursts of vigorous physical activity are beneficial to the child since they can spark the growth and development of the fundamental nervous centers in preschool children's brains. Sample activities of this nature include short footraces, jumping upward and transferring the whole body's weight into the air, and darting and dashing in imaginary plots that involve fleeing.

Moderate physical activity is more gradual and can be sustained for a longer period of time. Examples of moderate physical activity include stretching groups of muscles to imitate the life cycle of a tree, or by using their bodies to move like objects starting with a specific alphabet letter. Through moderate physical activities children explore novel ways to move, practice new motor skills, and learn to solve simple movement challenges. They also explore the movement associated with adult roles and work out their feelings through dramatic play such as the movements of a firefighter or farmer. Most preschool physical education lessons are based on a series of moderate activities, but also contain at least one to two vigorous activities depending on the amount of space in which the child can move freely.

The 2002 guidelines also discuss two key concepts for physical education teachers, caregivers, and parents. The first is *structured physical activity* that assumes the adult in charge of children will plan lessons containing activities that match infants', toddlers', or preschool children's developmental levels. The second term, *unstructured*

physical activity, is defined as "child-initiated physical activity that occurs as the child explores his or her environment" (p. 18). The concept implies that physical education teachers can serve as facilitators for the child's physical activity and exploration in the schoolyard or on playground apparatus that can offer a myriad of opportunities for climbing, stretching, and reaching. Playground structures not only enhance muscle growth, but also increase development of the heart, lungs, and other vital organs needed for optimal physical development.

An expanded second edition of the guidelines was published in 2009 with additional suggested activities. Greater attention was also given to health-related fitness in this document for children from birth through age 5 due to increasing evidence of childhood obesity beginning in the early years. This document again advocated for preschool children accumulating at least 60 minutes of structured physical activity, and engaging in at least 60 minutes and up to several hours of unstructured physical activity each day.

101 Tips for Physical Activity

In 2010, the national association for physical education published a booklet directly aimed at advocating preschool physical activity. The booklet was entitled *101 Tips for Increasing Physical Activity in Early Childhood*. In addition to the 101 tips to help teachers and caregivers plan physical education lessons and physical activity experiences, the document emphasized developmentally appropriate movement opportunities, maximizing the environment for learning, being creative with equipment, making safety a priority, and using techniques to enhance the child's social skills. It also emphasized providing instruction during structured play, integrating physical activity into the overall curriculum, and the need for teachers to be reflective, flexible, and willing to assist parents and families with information and resources. This easy-to-follow document is especially useful for new physical education teachers and caregivers, and it continues to stress the need for age-appropriate and purposeful

movement and physical activity experiences for our nation's preschool population.

PLANNING

Early childhood education (ECE) planning for teaching young children is a process that outlines ways of transmitting concepts and community values to children, sequencing learning experiences, and evaluating how effectively children receive this knowledge. Whether children's education includes schooling (formalized instruction), learning generated by children's life experiences, or knowledge and skill acquisition from both, the result enables children to become increasingly aware of themselves as learners and citizens in their world. A plan drafts the what, how, and when of learning. It is essential to achieving the goals of early childhood education. This entry outlines the history and importance of planning in ECE and further explores ECE planning in relation to several key educational theories on learning and curriculum

development (e.g., Ralph W. Tyler and Jerome S. Bruner's theories). It describes how ECE planning intersects with backward design, which influences related curricular approaches, and outlines how contextual factors impact major elements and principles of ECE planning.

Importance of Early Childhood Education Planning

ECE planning is important because it defines and describes curriculum and program expectations for young children's care and education. It makes teaching and learning intentional and transparent to the practitioner (teacher or caregiver), the learner, and others (managers, administrators, or a child's family members). The plans, along with the planning process, reflect the ideals inherent in the values of a community, such as the people within a community of child care programs, a school system, or a neighborhood homeschooling group. Similarly, the scope and sequence of concepts and skills to be learned by children, and prioritized according to developmental readiness, establishes what information is important to teach and learn. In general, a plan states goals, objectives, and desired outcomes—the learning and developmental expectations projected for each child. A plan lists supplies and materials as it describes strategies and procedures for implementation. Additionally, it states the boundaries of learning environments, such as the space, time, and setup. These details are critical to plan implementation and the likelihood for children's optimal learning. Finally, a plan assigns markers of success, which show the qualitative (nature of) and quantitative (magnitude of) measures of learning and development. Planning, whether for an individual child, a group of children, a program, or a school, is always drafted with the distinctive developmental needs of children as its foundation.

Historical Roots of Early Childhood Education Planning

The history of early childhood education planning begins with those who have had the responsibility

to care for and teach children on a daily basis. Both the parent/guardian, as the child's first teacher, and the professional caregiver and teacher, share the trust for a child's schooling and education. Today, teacher preparation programs embrace their part in this responsibility. In 2009, the most distinguished organization for guiding and accrediting both child care programs and early childhood education professional preparation programs, the National Association for the Education of Young Children (NAEYC) published a revised position statement titled, *NAEYC Standards for Early Childhood Professional Preparation Programs*. Of six preparation standards, *Standard 5, Using Content Knowledge to Build Meaningful Curriculum*, describes the expectation for teacher candidates to be able to plan appropriate and responsive curricula. It states that prepared candidates use their knowledge of child development and appropriate learning standards "to design, implement, and evaluate meaningful, challenging curriculum for each child." Further, the statement suggests that the large majority of teacher preparation programs rely on NAEYC standards for program preparation guidance. This may account for nearly all state departments of education's teacher candidate test's adherence to similar standards. For example, in cooperation with the Evaluation Systems group of Pearson, a test development division of Pearson publishing, states developed teacher exams that require teacher candidates to understand the principles of planning and delivering instruction that are grounded in knowledge of child development, motivation, alignment to standards, and providing adaptations for diverse learners. Further, this expectation and other professional criteria are codified in state educator rules.

Two distinguished scholars, Ralph W. Tyler and his successor, Jerome S. Bruner, have made important contributions to educational process and curricular planning. Their ideas resonate in early childhood education standards, research, practice, and planning tools. Tyler was an American educator whose contributions, in the late 1940s, include the ideas that schools and curricula should define educational purposes and useful learning experiences

that are layered to deepen understanding and sequenced to achieve goals. To determine success in student learning (or changes in understanding), he proposed a recursive, correcting process where areas that showed ineffective learning could be revised to improve outcomes. In the next 50 plus years, thinking about the best way to educate children changed. The enterprise of planning stretched beyond schoolrooms. Teachers, schools, and communities now partnered in planning. The diversity of children's languages, special needs, family cultures, and neighborhoods became important considerations. Accordingly, the nature of planning blossomed to include planning transitions and learning transformations for children. In 1960, Bruner, an American psychologist and educator, published *The Process of Education*. While recognizing the perpetual curiosity of children, he highlights the idea that learning is like a spiral, where reexamining concepts renders them increasingly understandable. He coined the phrase *spiral curriculum*, which labels this notion. His ideas grew from substantial research on how children think and learn, independently and with the help of others, to expand their knowledge base. Bruner's ideas suggest that a child learns continuously and can learn nearly anything, provided instruction is sensibly planned according to learner readiness, which is based on interest and past learning. Today, Tyler and Bruner's ideas are blended in the prevailing belief that the first step of planning is to identify the plan's ending results.

Backward Design in Early Childhood Education Planning

Writers such as Tyler, Stephen Covey, Grant Wiggins, and Jay McTighe emphasize that thinking with the end in mind is the heart of planning in *backward design*. Wiggins and McTighe, in their book, *Understanding by Design*, describe the three stages of this planning process as

1. identifying desired results,
2. determining acceptable evidence, and
3. planning learning activities.

In Stage 1, *desired results* include the goals for what children should know and be able to do in the context of state, accreditation, and curriculum standards. In Stage 2, *acceptable evidence* includes information obtained from observing and recording learner actions that shows recognition and evaluation of understanding. Both formative (along the way) and summative (at the end) assessments of demonstrated competencies or skills are acceptable evidence. In Stage 3, *learning activities* include experiences within and between the parts of the activity, with attention to the developmental and learning readiness of learners to achieve the goals of Stage 1. Like applying any plan model to a goal, it is important to note that backward design first leads the planner through a thinking process, then through a writing or recording process. The final plan, whether finalized on paper or electronically, may or may not be formatted to mirror the stages of the thinking process. Typically, ECE activity or lesson plans, for example, are recorded in a deductive (top-down) format, and, likewise, communicated to children and others in straight-line fashion. The inductive logic of backward design captures the intuitive or developmentally driven thinking of planners (adults or children with adults), making it a popular model for planning short- or long-term learning adventures.

Designers and Recipients of Early Childhood Education Planning

The designers of plans for early childhood education learning may include educational administrators of schools or programs, teachers, or teams of practitioners and parents/guardians who differentiate learning experiences for diverse learners. Additionally, designers include writers of published curricula that promote research-based approaches to education, such as the project approach, Creative Curriculum, Montessori, HighScope, or Bank Street. Whether purchased or practitioner-designed, planning for young children's learning is often characterized by the degree to which it is teacher-directed or child-directed, thematic, exploratory, emergent, or a

hybrid of one or more models. Because inductive thinking generates and drives planning, it is important to consider children, the learners themselves, as contributors to the planning process. Emergent learning or emergent curriculum is a process whereby children's interests pose the topics through which learning will occur. In this regard, children inspire the planning while the teacher retains responsibility for facilitating and assessing the learning, even when assessment is carried out in partnership with children. The recipients of the planning process include the child learner, the parents/guardians, the caregivers/teachers, and the program or school community. All expect that early childhood education planning will support linguistic, economic, and even political cultures that surround their involvement in educating young children.

Contextual Factors of Early Childhood Education Planning

Contextual factors influence ECE planning by framing the purpose of plans. Some universal factors include time, the economy, or political circumstances surrounding education. More specifically, a child's developmental status, how children are grouped for learning, program licensure requirements, program and school accreditation standards, and physical setting characteristics affect the direction and breadth of planning. Additionally, the social aspects of the child's world, such as language, family lifestyle, and community culture, are contextual factors that amplify the relevancy of ECE planning. Finally, a caregiver or teacher's education, training, and creativity inform the planning process. While some factors may be disruptive to planning or plans, like staffing changes, temporary lack of resources, or emergencies, planning flexibility can lessen negative effects or inspire solutions to problems. In varying degrees, then, contextual factors affect form, function, and recipients of plans. Contextual factors are complementary and contribute both distinctiveness and depth to responsive plans that meet the needs of children and programs alike.

Elements and Principles of Early Childhood Education Planning

In order to tame influences on planning, early childhood education practitioners follow a set of steps that makes their intentions visible and enables them to prioritize their thinking. This process leads to ordered actions, and intended outcomes—the best of plans. If the plans result in unintended outcomes, the practitioner uses these surprises to fine-tune plans. In ECE, the initial planning process and subsequent replanning reduce the chance for unexpected results. The planning process includes five basic elements and three common principles, some of which may be condensed or elaborated according to who uses the plan—children, practitioners, family members, or policy makers. ECE planning elements include determination of the following:

1. goals—a broad statement of what is to be accomplished;
2. rationale and preconditions—the basis for teaching, including what the child knows and is able to do, developmental milestones and learning progress, and features of the educational setting;
3. method/procedures—sequence of engagement steps with supplies/materials and people;
4. outcomes—the expected knowledge and skill acquisition (linked to children’s physical, social-emotional, and cognitive development); and
5. evaluation—an experience or competency appraisal that reveals progress and next steps for achievement.

The planning principles, embedded in the planning process, include the following:

- attention to children’s unique developmental characteristics shaped by age, disabilities or special learning needs, and family culture;
- alignment of plans with state and/or accreditation education standards and ethical practice; and

- appropriate use of a planning device to set priorities, such as a web or learning map, a timeline/calendar of learning activities, or a table or a list of learning experiences.

Applying Elements and Principles of Early Childhood Education Planning

The planning process relies on a logical flow of events that supports the well-being of each child. Practitioners spend time learning about children’s educational and developmental history, families, and communities in order to set reasonable expectations for children’s learning. Goals and rationale are adjusted to accommodate children’s linguistic, developmental, or special needs according to the education standards of the setting. If the needs meet the criteria of the Americans with Disabilities Act and the child is under 3 years, an individualized family service plan (IFSP) will be developed. For an older child, an individualized education program (IEP) would be adopted. Correspondingly, the elements of indoor and outdoor learning environments pose time, space, and condition parameters that control the timing, methods, and materials of instruction. As part of the planning process and during implementation of plans, practitioners may blend procedures and setting features in unique ways to achieve extensions to learning. Procedures used indoors might be suitably extended to the outdoors (painting or storytelling, for example), while running games or nature walks are only *virtually* possible indoors with technology. All outcomes present opportunities to keep track of mistakes and successes. When the logical flow of the plan is compared with outcomes, a loop is closed and lessons learned inspire new goals, affirming children’s capabilities and competencies.

PLAY, BENEFITS OF

Play is visible in various actions, expressions, movements, and ideas of individuals and groups. It is more clearly recognized and labeled than it is defined. While it is difficult to pinpoint the exact meaning of play, it is possible to examine the benefits of play in early childhood education, growth, and development.

From birth, children are actively exploring their world. They utilize their senses to form an understanding of people, places, and things with which they come into contact. This active engagement provides avenues for learning that help to expand the development of the child. Through play, a child's development is positively impacted in all domains: cognitive, physical, social, and emotional.

Play Benefits and Young Children

Play and playful behavior have positive effects on the development of the brain and the child's ability to learn and develop. According to Sigmund Freud and Erik Erikson, play helps children master anxieties and learn to resolve conflicts. Tension is relieved in play and children can cope with life issues. Jean Piaget and Lev Vygotsky viewed play as a medium to advance cognitive and social

development. Through play, children practice competencies and skills in a relaxed format. Imagination and creativity are advanced through symbolic and make-believe play.

Play helps to satisfy the exploratory nature in each human being. Through play, children can safely explore and seek out new information. Play also helps children explore gender roles and organizations in society. Social skills and friendships are developed during play. Functioning as a crucial skill in the lives of children, play helps them as they learn and grow cognitively, physically, socially, and emotionally. It is a primal ability that all children have from birth and all children use to investigate and make sense of the pieces of life that occur each day.

Children naturally explore through playlike formats. They use their senses to discover and form understandings of the people, places, and things around them. Play serves as an engagement tool and an avenue for learning. Through the inborn mechanism of play, children expand their knowledge and understanding in all developmental domains. Their curiosity and imagination tie with social information and facts. Equally important, play is a common ground for all children across cultures. Play serves every economic class, ability, and learning style.

Play and Cognitive Benefits

Play provides a setting in which children are able to actively explore their world. In relation to cognitive development, the benefits of this exploration are clear. Play provides the meaningful context through which children are able to practice and make sense of new concepts and by which they construct new understandings and knowledge.

In exploratory play, children repeat a newly acquired skill to reaffirm their ability to complete the task. They will repetitively put the block through the correct hole or pour the water out of the cup. This is a simple task that is replicated for the joyful experience of individual success. This type of play continues in importance throughout development as even adults will repeat a pleasurable experience

because it makes them feel good and successful. As adults, people find ways to experience and repeat aspects of life that bring them joy. It is this type of playful action that brings peace and relaxation to a busy schedule. This is crucial to cognitive development over the life span.

Exploration of objects is different than exploratory play. Through exploration, children discover properties of tools or items. This gives them a way to make sense of how things work and what things do in the world. The goal is to figure out something through the exploration of play. This leads to cognitive development and understanding of the physical world. By having firsthand experiences with real objects, children will form concepts that are more meaningful and easily remembered.

Through constructive play, children use objects or resources to represent something different than the actual object. This may also be referred to as representational play. Children use blocks to represent a road or a train track. They may take a block into the dramatic play area to represent a salt shaker on the table. This type of play becomes more complex as children develop.

Constructive play leads into dramatic play, during which children create imaginary situations and take on various roles. Representational play is part of the dramatic play as items are used as symbols of objects in the play episodes. The mental transformation of objects is the beginning of literacy and numeracy development. As children begin to engage in such play, they also begin to understand abstractions. Dramatic play promotes abstract thinking, which is the basis of literacy and math development.

In sociodramatic play, children can develop written play plans as well as determine the theme, settings, roles, and rules of the dramatic play period, as discussed by Elena Bodrova and Deborah J. Leong in their 2007 book, *Tools of the Mind*. Children who are involved in this type of play have been shown to score higher on literacy skills than children who are not in classrooms of these types. Children who engage in pretend play have higher school readiness scores. Play promotes risk taking, allowing children to go beyond their capabilities

without the fear of being judged or worrying about the consequences. Children must take risks to learn, and through play, children easily take those risks.

Young children work hard at play. They invent situations, solve problems, and negotiate roles. In play, children are highly motivated and fully engaged. In sociodramatic play situations, children are found to have greater language skills and social skills. They are also able to show more imagination than nonplayers. It is evident that there are connections between play and foundational capabilities. These are found in the development of memory, oral language abilities, and success in school. It is crucial to value and encourage the self-directed activities of young children and scaffold imaginative play in early childhood experiences so children develop the continued advanced play that contributes significantly toward cognitive development.

The benefits of play for cognitive development have been shown by play researchers. As children practice newly acquired skills, they gain confidence and form a sense of self-competence. Children require firsthand experiences with objects to explore them and understand their properties. Through play, children take risks and move toward increased cognitive development. Play is crucial to school readiness and continued school success.

Play and Physical Development

Play provides a physical release and helps children form friendship bonds and cooperative prosocial behaviors and attitudes. Outdoor free time with peers facilitates friendships and helps promote quality social skills that carry through to the learning environment. Young children must have the release time of physical play in order to release stress, balance mental connections, practice physical skills, and form social connections.

The value of play connects to children's health. Play allows children time to practice and develop fine and gross motor skills. Physical activity promotes early brain development and learning and decreases the risk of health conditions such as hypertension, obesity, heart disease, and diabetes.

Play provides various benefits to the overall health and well-being of children.

Brain development is impacted through play. Connections of the prefrontal cortex are changed through play experiences and help wire the brain's executive control center. This performs a critical role in cognitive development. Through play, children are developing rules and negotiating while the brain builds new circuits to help navigate the complex social contexts. Research also shows that when children are provided unstructured brain breaks during learning, they make positive gains in their ability to attend to and retain more information. To illustrate the need for play, research shows that the brain breaks must be unstructured free play, without direction from adults.

Over the past few decades, the increase of childhood obesity has been well documented. As this epidemic has been on the rise, there also has been a decline in physical and outdoor play by children. Young children spend less time in unstructured and unscheduled physical outdoor playtime than they once did. In today's technological and media-based society, young children often spend their "play" time sitting still at a screen playing games. Unstructured play provides physical activity time that children need to grow and develop healthy bodies.

Play and Socioemotional Development

According to some qualitative research, instances of aggression in young children are on the increase. Schools struggle with children's social behavior and lack of ability to control emotions. Children spend less time on the playground chasing each other in simple games of physical release or testing their strength and abilities on climbing equipment. Recess and unstructured free time with peers has been reduced or removed from the daily schedule in schools but aggression and social skill issues have increased.

Through play, children are able to work out the rules for social interaction and to determine how to be at their best in each unique situation. Play is the vehicle for building social competence in early

childhood and allows young children to practice and gain confidence in their social skills with peers.

Play is crucial to the development of self-regulation and the ability to manage emotions. Through play, children are able to practice these skills. Children adopt the roles and perspectives of others in play and begin to internalize the rules of social behavior. Through make-believe play, young children act as the "parent" or "teacher" and practice reactions and emotions of situations. They use play as a means of working through the emotions they experienced in circumstances with others. Play helps children cope with change and new experiences in a context that allows them to make sense of the situation in their own way. Play is a way to reduce stress and anxiety for children.

Play allows children to learn to be part of a group. Through play, they develop the social skills of negotiation, collaboration, problem solving, and sharing. Children develop friendships and social connections during play while practicing basic social skills and developing a sense of self. It is through play that children develop their social competence and emotional security.

Emotional development is impacted through play as it provides an avenue for children to express and cope with feelings. Pretend play allows children to simplify events to match their emotional state and make sense of the situations that they face. Children also learn to control emotional expressions by repeating events through pretend play that are unpleasant in real life. Play allows children to cope with feelings by acting them out in playful episodes.

Play is the natural inborn mechanism through which children explore and gain meaningful understanding of their world. It is through play that children learn and advance in all developmental domains: cognitive, physical, social, and emotional. The active engagement of play provides children the means to learn and grow naturally and with their own unique motivation and direction. While each child may have varying interests in play, the values and benefits of the acts of play are the same as they work toward the development of the healthy child.

play and adult roles in the play of young children. Alternative positions, such as “trust in play,” “learn and teach through certain forms of play,” and “keep play out of the curriculum” can and do influence how teachers use provisions and their expertise to influence play.

Underlying philosophies and conceptual schemes impact common curricular features of ECE programs such as the availability of materials, organization of space, and daily schedule, as they likewise influence teachers' decisions regarding whether or how to borrow from comprehensive curriculum models such as HighScope (e.g., plan, do, review cycle) or from well-known specific play intervention strategies or techniques (e.g., sociodramatic play). Adults' beliefs and values about play, learning, and development that are embedded within these guiding orientations are contributors to teacher decisions and actions leading to proportions of child-initiated, teacher-facilitated, and teacher-directed play witnessed within ECE programs.

An extreme and rarely seen position on play and the ECE curriculum is *segregationist* in which no attempt is made to use play for classroom learning; only recreational play is allowed at recess or break times. The *juxtaposition* model pairs playtimes with instructional times with some thematic connection made between the two, such as equipping play centers with props or content in line with ideas taught during formal lessons. The *integration* model seeks teachable moments during child-initiated play to guide learning and exploration and represents a blending of play and learning.

Two additional schemes adhere to the acceptance of play within the ECE curriculum seen within the juxtaposition and integration models: curriculum-generated play and play-generated curriculum (Van Hoorn, Nourrot, Scales, & Alward, 2011). With the first curriculum-generated play scheme, the teacher provides opportunities for play in accord with curricular goals. The curriculum objectives are the drivers, and children's play is subordinated or following from them. For example, a teacher may set up a numeracy-enriched store in the dramatic play center to consolidate

PLAY, CURRICULUM, AND PEDAGOGY

Different schemes illuminate how ECE programs can use teaching with play and learning during the early years. Those teaching children are divided over whether play has educational value, and if so, what kind of play has value—with these differences reflecting educational philosophies about

number and space concepts that were formally presented in a lesson at another time of the day or week. This scheme or model affords individualized teaching in contrast to whole-class teaching. Additional instruction is given only to children who still need to learn the skills following play experiences. Academically enriched play centers, games, and simulations are used in this model. Their employment is determined by the overriding aims of curriculum.

The play-generated curriculum model contrasts with curriculum-generated play. Play by children is used to build learning goals. In this model, play comes first and curriculum follows. Still, within child-initiated play, with or without teacher scaffolding, students can and do learn or practice concepts and skills relating to academic content areas, such as science and social studies (via *curricular networking*). Children are engaging in a series of events that are not set up in advance but are flowing out of their playing and learning experiences. What they learn in play is spontaneous and unplanned in a sense. However, teachers can deliberately plant valuable learning embedded within or following the play episodes. Here play is the source of the curriculum or is the curriculum and shapes the learning experiences.

Pedagogy of play or play pedagogy within ECE is teaching and learning using play as the medium or context of these important instructional and communication processes. It is expressed in curriculum configurations, marked by coconstruction by teachers and children, and in the use of child-initiated play together with teacher-guided or facilitated play. Teacher support and scaffolding of play occur through the exercise of various teacher's roles in play, such as carefully observing play in order to effectively stage manage before and during play, help in play negotiations, mediating peer conflicts, making suggestions for children to sustain or elaborate their play, scripting their play for later teaching, and the like.

Rationale

Many scholars (see Johnson, 2014) and advocacy groups such as the Alliance for Childhood assert

that play pedagogy is critical to the success of ECE's current quest to escape from overly teacher-directed academic models of the ECE curriculum and from curricula that are too loosely structured, prone to cater to child wants and interests without learning value for the young child. This move toward balance positions ECE to construct play-based curricula as avenues for fostering young children's intellectual development, self-regulation, prosocial tendencies, and social competence in ways that do not neglect important areas of children's lives, such as their physical and emotional well-being, imagination, and creative expression.

Play pedagogy is instantiated in teaching practice in many diverse ways but always includes balancing the teacher's and child's agenda, serving the cognitive and emotional needs of children. Ingrid Pramling Samuelsson uses the term *playing-learning child*. Teachers seek to use arrangements and social opportunities in ECE settings that bring to the fore playful components in learning and learning components in play.

Play pedagogy encompasses playful classrooms with focused learning as well as classrooms rich in child-initiated play. The goal is to avoid didactic, highly structured classrooms in ECE and ones that have play but low-quality play because the teachers are not actively involved in enhancing play. Teachers can accent learning with play by using the juxtaposition model or can foster it by blending it with learning using the curriculum integration model discussed earlier, either with curriculum-generated play or play-generated curriculum. Play pedagogy also includes methods that are more teacher directed.

Examples

Teacher-directed play methods are embedded within an existing classroom in order to enhance playing and learning experiences. They are different from teacher-facilitated play in that they instigate structured play and are not just responding to child-initiated play. Many are teacher directed in the setup of provisions and teacher facilitative interventions once the children begin to play.

Contingency play teaching prevails in that as children manifest more play prowess the teachers back off and let the children play more independently. Several well-known varieties of play pedagogies are briefly described.

Sociodramatic Play

Sara Smilansky pioneered *sociodramatic* play (SDP) training targeting young children with play deficits. Adults intervene with book reading and they should also do so with play props and ideas. SDP is a developmentally appropriate way to prepare low-income preschoolers for formal schooling through its demands for symbolic and abstract thinking. SDP is verbal make-believe play in a group, lasting at least 10 minutes. Students take on make-believe roles in another time and place while employing real, substitute, or invented play props. Teachers familiarize children with the topics of their scripts and roles by taking children on field trips, bringing in guest speakers, reading books, or having class discussions. Teachers observe the children playing to decide which children need help to exhibit the qualities of SDP. The teachers foster SDP through modeling, making helpful comments, questioning and coplaying, gradually reducing their support as children increase their ability to perform SDP independently.

Thematic-Fantasy Play

Thematic-fantasy play (TFP) was first employed by Eli Saltz and James Johnson and is similar to SDP, but the content is not life events but fairy tales such as *The Three Bears* or *The Three Little Pigs*. Teachers read and discuss the stories with the children, simplify the plots as needed, and set up a space for enactment with suitable props on hand. Teachers assign roles, take on a role, and serve as the play director.

Playworlds

A famous play pedagogy from the Nordic states is Playworlds, researched by Pentti Hakkarainen and others. In Playworlds, children are led by their teachers during group dramatizations of fictional events inspired by classical children's literature and

fantasy history, such as playing knights, castles, and dragons. Academic school subjects are connected to the play as young students follow projects and investigations related to the geography and history of themes, studying maps and employing mathematics, science, and reasoning skills while building cognitive and narrative intelligences.

Literacy-Enhanced Play

Similar to SDP and TFP, but adding an emphasis on literacy, *literacy-enhanced* play pedagogy implements centers equipped with extensive materials for pretend writing and reading, such as pens and markers, paper, notepads, books, and magazines. Environmental print, such as travel posters or advertising, is displayed. Teachers are active in displaying and encouraging the functional use of print within play enactments, such as using the menu or writing down an order for lunch at a pretend restaurant.

Storytelling and Story Acting

Another play pedagogy targeting literacy, narrative competence, and community building is Vivian Paley's *storytelling and story acting* methods in which the teacher-as-scribe, at a story table set up during free play, records child-authored stories that are later enacted on a classroom "stage."

Improvisational Methods

Improvisational methods recommended by Carrie Lobman and others assume a performance stance toward human development rooted in Vygotskian theory of creativity, symbolic play, speech, and language. Improvisation play pedagogy requires an openness to others and affirmation of others through saying *yes* to their social bids in a way that is also satisfying one's own individual interests and needs for agency and creative expression. Spontaneous play undertaken by teachers and children follows spur-of-the-moment feelings and thoughts and not prescribed content or plans. The use of improvisational play pedagogy can build positive teacher-child and child-child relationships in inclusive classrooms.

Group Games

Group games contrasts with the other pedagogies in its focus on constructive and game play. Constance Kamii and Rheta DeVries, influenced by Piagetian theories, recommended traditional games in the ECE classroom as a way to support children in learning rules and taking the perspectives of their peers and the teacher. The role of the teacher includes guiding children in their thinking and conflict resolution by asking thought-provoking questions. The aim here again is to assist the play process itself as well as the learning benefits associated with the play.

Issues

Use of play pedagogy models and interventions can imply play and learning deficits. This relates to the so-called gap versus DAP debate, or how to have developmentally appropriate practices (DAP) and also reduce the achievement gap and school-readiness issues that exist between children from families with higher and lower social and material capital. Some children seem to require more program structure and teacher direction than do other children from more privileged backgrounds who can enjoy more open framework curricular opportunities for genuinely enriching play. A social justice issue looms when a disproportionate number of low-income children find themselves in classrooms with more structured play opportunities only, or worse yet little or no play because teacher-scripted and led instruction and testing and practice for test taking have elbowed play out of the ECE classroom.

Recently, a learner-inclusive play pedagogy has been recommended. David Elkind distinguished between the teacher's functional perspective and the child's experiential perspective on play in the ECE curriculum. Coconstructed inclusive play pedagogy brings both into the picture. Coconstruction of play pedagogy sees the teachers and children interacting together and the relation of playing and learning as occurring on two levels—the teacher level and the child level. The interplay of play and learning is a figure-and-ground problem in a learn-

ing encounter in the classroom, involving the teacher (learning goals and curricular objectives) and children (playing and doing).

Ideologies and policies can stand in the way of teachers actualizing their intentions and understandings of pedagogies of play (Wood, 2014). Elizabeth Wood warns about “eduplay” and the “technicist” vulgarization of play pedagogy that reduce it to an expression of a “teaching to the test” mentality in which play becomes pseudoplay and is set up to happen primarily to serve the teacher's need to check off that an early learning standard objective has been met for the day. Such preordained fraudulent play must be eschewed in implementing and seeking the promises of play pedagogy as a contemporary curricular movement in ECE.

PLAY, DEFINITION OF

Play is a jumbo category, a big umbrella term. Since so many different actions, expressions, movements, and thoughts are called play, a singular definition of the construct is not possible. Play is easier to describe or to indicate by example. Any definition of play is not true or false but useful or not useful for a given situation or purpose, such as found in a specific research study or early childhood program.

A popular approach in early childhood education (ECE) research, policy making, and practice is to characterize play as mental or physical activity that possesses certain attributes. Many scholars have pointed out that in ECE an overt action or expression is more likely to be called play if the expression meets the additive criteria of possessing accumulating attributes commonly accepted as reflecting play qualities. These include the following: playful thoughts and playful activities are (a) accompanied by positive affect, (b) freely chosen, (c) under the primary control of the young child, (d) are motivated by the play itself, (e) ones for which the meaning is primarily determined by the young child, (f) nonliteral and dynamic, (g) in need of relaxed circumstances or a less stressed mental frame, and (h) reciprocally related; that is, play actions and play thoughts build on one another.

How ECE defines play has been informed by philosophy and the scientific study of play. For example, Roger Callios in *Man, Play and Games* (1961/1958) identifies vertigo, competition, mimicry, and chance; he discusses these play forms and their combinations along a continuum from freer (*paidia*) to more controlled (*ludus*) play. Play is uncertain, rule bound, fictive, unproductive, free, and separated from reality. Johan Huizinga's *Homo Ludens* describes play activity as voluntary, not serious but very absorbing, without material gain, rule bound, conducive to social belongingness, and framed from reality.

Philosophical views now also incorporate seeing the postmodern world at play; play is not so much an escape but a response to life. The experience of

uncertainty, diversity, and change is dominant today and affects ECE. Play's quirkiness and flux, its nonlinear back-and-forth quality (*Spiel*, the German word for play, also means "to dance") is a kind of binary code in the software programs for imagination, creativity, and problem solving so crucial to meeting present-day challenges and future unknown realities.

Gordon Burghardt's 2005 *The Genesis of Animal Play* states that play behavior occurs when (a) the organism is safe, relaxed, and free from extreme wants; (b) play is *autolectic* (i.e., spontaneous, voluntary, intentional, and often pleasurable or rewarding); (c) often observable as repeated behavior; (d) not purposeless but also not entirely functional in the context expressed; and (e) often exaggerated in expression and incomplete as final functional elements are dropped. Although coming from biology with animal play in mind, these five attributes resemble ones on lists more commonly deemed useful in ECE.

Play Concepts in Early Childhood Education

ECE theory and praxis is concerned with a rather narrow subset of the wide range of known play manifestations. Children's play with their bodies, objects, symbols, and others is considered in schemes used by researchers and teachers to account for it. For example, in ECE, play that is solitary, parallel, or socially interactive is often nested with physical, functional, constructive, dramatics, or games-with-rules play forms to track both the sociality of play and its cognitive form. Block and puzzle play (constructive), simply using toys (functional), or enactments with dolls, puppets, or dress-up clothes (dramatic) can occur when the young child is alone (solitary), near another child playing similarly (parallel), or in social commerce (interactive, which can be merely associating or, on a higher level, cooperating with peers).

School-sanctioned, academic or *educational play* is defined as play that is initiated, controlled, paced, terminated, and assessed by the teacher for

its educational merit. Educational play is a planned part of the curriculum, joining deliberate investigations and expository teaching/receptive learning as pathways to developmental enrichment in the classroom. Play purists question whether educational play is genuinely play since it is not intrinsically motivated behavior but motivated by the relationship children have with their teacher.

In contrast, *everyday* play is recreational, outside teachers' influence; such "real play" or ordinary play is more likely to happen during free play, at recess or at other times on the playground, or when the child is at home. Such ordinary play can be cooperative, competitive, illicit, defiant, even mildly or moderately gross, foul, or mean-spirited. To remain play, however, there must be reciprocity and respect between or among persons. Accordingly, bullying cannot be defined as play; but superhero and power play can be viewed as play since the aggression is not real but only thematic. In ECE, a primary concern is with educational play (e.g., documenting classroom play) and a secondary concern is with recreational play (e.g., advocating).

Developmental or age-related play is a major concern and target in ECE programming and teaching. To simplify, infants engage in a great deal of exploratory play and imitative play with objects—solitarily, socially with peers, or with caring parents or teachers. Toddlers, much the same as infants, enjoy face-to-face playing with objects, doing finger-plays, singing, and the like. However, they are growing up and are exploring a wider world and showing increasing autonomy in their play behavior. During the preschool years, the children continue to develop and are seen often building with blocks; using icons and numbers and letters in computer play; performing social pretense, dramatic play, or imaginative play with objects; or playing simple games with rules.

Both Jean Piaget and Lev Vygotsky provide arguments for the importance of play in ECE. Piaget views play as assimilation (i.e., bending reality to fit preexisting cognitive schemata) in complement to accommodation (i.e., modifying cognitive schemata in response to incoming information). Both processes work in tandem to

achieve adaptation. Accommodation generates new learning, while assimilation integrates it and makes it more meaningful.

In ECE when the child is imitating or exploring, he or she is engaged more in accommodative behavior than in assimilative behaviors. Imitating or exploring is more stimulus oriented, while playing is more response oriented. In the former, the child is asking, "What is this?" but the playing child is asking, "What can I do with this?" Often, these behaviors form a pattern as the child examines, reexamines, and transforms objects. Some ECE authorities refer to this as epistemic play (investigative behaviors) and ludic play (pretense). Play is a dynamic state and seldom are children exclusively playing for an extended period of time; there are admixtures of play and nonplay and playlike behaviors, such as imitation or investigation or "work" happening within a typical play period or episode.

Play and work can co-occur in a complementary and dynamic way. Play can become work, and work can become play. But play is not the work of children according to this line of reasoning. Play can be better viewed as an occupation of childhood, just as loving and feeling loved are important ways of the young child being in the world. In addition, the opposite of play is not work; negation of the play spirit produces or is caused by psychological depression. Depression is the opposite of play.

Vygotsky views play as a way of self-scaffolding in the zone of proximal development, enabling the child to perform at a level beyond his or her developmental stage, which propels learning and development. The teacher or an older or another child "play expert" can also scaffold a child's play. To do this effectively, the teacher or expert needs to recognize the difference between the *play frame* and the *play script*, or the context (frame) and the text (script) of play. What children do within the play frame is *play enactment*; what they do outside the play frame often is *play negotiations*. While the former are the actual play actions, the latter are discussions about the play, deciding which roles each child will have, what props or substitute objects will be employed, and where and when pretend or real actions will occur.

Play facilitation strategies or interventions designed to enrich and extend complex social role play, for example, demand recognition of the invisible boundary surrounding play, the magic circle of play as it is sometimes called, from the actions and words that are taking place outside this boundary; or play context affects the play text. Without the auxiliary concepts of play frame and script, context and text, and play episode, an ECE teacher or researcher cannot adequately observe, interpret, and analyze children's behaviors to discern the meaning of children's actions. These play concepts and terms are also indispensable for description and commentary in play assessment and documentation.

Play is potentially influential in the development of early symbolization, self-regulation, and social competence and in meeting mastery and control needs the young child cannot satisfy in reality. Some benefits are not a given but are a function of the quality of the behavior. One major type of quality play is mature role play, which is a leading activity, or an activity that plays an essential role according to the theories of Vygotsky. To explain, close emotional communications is the most consequential or leading activity for the infant and toddler's psychological development; after 6 years, mastering the disciplines of academic subjects is the leading activity for mental development. The leading activity for preschoolers up to 6 years old is mature role play since it is invaluable for constructing an understanding of the social world.

Mature role play is high-level play in contrast to low-level "immature role play" marked by children's quarrels over toys, restricted speech, overreliance on realistic toys, and short and erratic play episodes. Mature role play makes the child appear, as Vygotsky (1978) put it, "as though he were a head taller than himself" (p. 102). The following attributes are present: (a) there is an imagined situation; (b) the pretend situation follows implicit rules from cultural scripts (e.g., enacting "grandma" requires knowing and following social norms about the role of grandma); (c) explicit roles, such as overt enactments of self and other person transformations (e.g., "I am Batman, and you be Robin."); (d) object and situational transformations, as in the

use of real objects or substitute or invented or imagined objects or props for make-believe play, and use of language to transform time and space (e.g., "Let's pretend it is in the middle of the night and we are lost in the forest."); and (e) sustained play over time and even days in the same play theme.

Here role play is privileged as the leading activity from 3 to 6 years. But one can extract from *quality role play* key features such as elaboration, persistence, concentration, verbal interaction, and social reciprocity and judge whether they are present in other *quality play*, such as game play or constructive play. What is important to take from this is that in ECE quality play is the aim, not just play. Although defining quality play is difficult, such play usually reveals some planning, social cooperation, and verbal elaboration.

Conclusion

Distinguishing play and playlike behaviors from other behaviors, and being able to judge more mature or developed play from less developed or immature play, are important skills to possess for accountability in ECE practices and policies. Since play defies any simple straightforward definition, the field grapples with the notion of play by delineating its attributes, types, development trajectories, potential benefits, and criteria for quality play.

By having within one's professional working vocabulary a clear understanding of the play concept, and its auxiliary concepts (e.g., frame, episode, negotiation, enactment, exploration, imitation), the ECE practitioner can more effectively engage in intelligent conversations about play with colleagues, administrators, policy makers, and parents. Play advocacy, play assessment, and play documentation also require a good dictionary as a conceptual base—all of which can help restore and sustain play's importance in the field.

PLAY, NATURE OF

Childhood play defies definition and some researchers even refuse to try to define it. While the Eskimo have 50 or more words for *snow*, the English language's singular word of *play* encompasses many childhood and adult activities. Is playing dressing up, building blocks, finger painting, kicking the ball on playgrounds, swinging a bat at a baseball, or manipulating the keys of a piano? While societies have been studying childhood play for centuries, dating back even to Plato and Aristotle, there have been various theories about why children play. This entry first discusses various theories about play that have been commonly held in the past, as well as more recent theories. It then discusses the various types of play children engage in and the functions they serve.

Theories About Why Children Play

Pre-20th-Century Theories

- *Excess Energy*—A child has too much energy and active physical play actually eliminates the extra energy from the body, wearing the child out.
- *Relaxation or Replenish Energy*—Playing allows the mind to destress and relax and recharges the body with energy.
- *Evolutionary Recapitulation*—A biologically based theory that stated children go through the same play sequences that all mammals experience with increasing time and complexity spent in childhood play the higher the order of animal and the level of civilization.
- *Instinct-Practice*—Play is for learning future adult roles: for example, mother, father, teacher, or cook.

Twentieth-Century Theories

- *Psychoanalytic*—Symbolic or pretend play is cathartic, actually relieving the pain and trauma of everyday events or disturbing situations—spanking doll baby, giving the stuffed toy a shot, pretending to be the mean sibling.
- *Cognitive Development*—The purpose of play is to construct knowledge or cognitive concepts through the manipulation of materials in the environment such as blocks and other toys and through interactions with other adults and children.
- *Functional Play*—Play is for the sheer joy of doing something over and over again, such as swinging, hopping, skipping, or tapping fingers on the table.
- *Construction Play*—Play has a defined purpose: for example, building a fort in the block area, making a prop for a play theme, or painting a picture.
- *Symbolic Play*—This type of play involves a representation of an absent object: for example, pretending there is food in the dish and eating it, or dialing a telephone in the air.
- *Sociodramatic Play*—This is a more engaged type of pretend play that involves both interactions with other children and the use of props and symbols; it is considered the most highly developed form of play.

Twenty-First-Century Theory

- *Neural Evolution*—This new theory holds that play is the medium that actually connects the brain cells in order for one to make sense of the world.

All theories of play are accurate to some extent. The neural evolution theory, however, combines all the theories into one all-encompassing explanation of how the brain cells connect, thus making sense

of everything from concrete knowledge about the environment and construction of cognitive knowledge to emotional intelligence about one's intrapersonal self. In studies of animals, researchers found that animals that played longer in "childhood" had larger brains. In fact the larger the brain, the more apt that animal was to survive its environment's challenges. Recent research on brain size of deprived and vulnerable children reports that their brains are smaller in mass than those of typical children.

Types of Play

Maria Montessori is often credited with saying play is the work of the child. No early childhood educator would deny that children learn through play. There are many types of play, however, and neuroscientific research is showing that not all play is equal. Table 1 gives some examples of different kinds of play found in preschool and kindergarten classrooms and what children are learning.

Table 1 Types of Play

<i>Type of Play</i>	<i>Materials</i>	<i>Outcomes</i>
Construction play, wood-working	Blocks, LEGOS, lumber, cardboard, building supplies, boxes, etc.	Math concepts, fine motor skills, balance
Creative play	Easel painting, other art mediums such as clay, Play Doh, markers, etc.	Science of color, shape, design, aesthetics
Manipulative play	Beads, beans, junk	Sorting, classifying, fine motor skills
Sand and water play	Sand/water table or outdoors, shovels, buckets, watermills, etc.	Texture, volume, science
Play with symbols	Materials found in language/library/writing center	Use of symbols on paper
Exploratory play	Just about anything: Snow in a bucket, planting a seed, what's in the picture, one square foot of the playground grass	Curiosity, investigation, problem solving
Gross motor/active play or functional play	Running, climbing, throwing, swinging, sliding	Large muscle development
Oral language play	Songs, finger games, poems, and rhymes like "Joe, Joe, Bo Bo, Banana, Nana, Fo, Fo . . ."	Rhyming words, phonemic awareness, vocabulary
Music play	Instruments both homemade and purchased	Rhythm, beat, tune
Games with rules	Duck, Duck, Goose; <i>Candy Land</i>	Rules, one-to-one correspondence, taking turns
Dramatic play	Acting out a story	Recall, sequence of story, vocabulary
Pretend/sociodramatic play	Spontaneously acting out a situation/event	Language, creativity, rules, roles, flexibility, self-control, perspective

Source: Table, pp. 8–9, in Guddemi, M., & Selva, G. (2014). *Pretend play and brain growth: The link to learning and academic success*. New Haven, CT: Gesell Institute of Child Development.

Sociodramatic play or pretend play with others is considered the most mature form of play. During this type of play executive functioning skills are being developed. Executive functioning skills are focus, persistence, problem solving, creativity, cooperation, curiosity, ability to delay gratification, flexibility, and more. These skills are associated with school success. Furthermore, higher levels of executive functioning skills better predict school success than IQ. MRIs of the brain have shown that children who have mastered mature sociodramatic play have more neurological connections in the prefrontal cortex where executive functioning skills are housed.

Piaget proposed the following characteristics that define *true play*:

- exists for no clear purpose,
- spontaneous,
- engaged in for pleasure,
- lack of organization,
- free of conflict,
- contains elements not found in the real world (symbols),
- lasts for at least 10 minutes, and
- includes language and interaction.

Mature sociodramatic play takes on additional characteristics:

- Must be with two or more children
- Deep engagement
- Planning the play event
- Rules for each role

Based on these characteristics, construction play would not be seen as play.

Need for Play

Researchers have documented that children play less today overall, play less outdoors, play less at home due to “screens,” play less at school in the classroom, and have little or no time to play at recess. These are alarming trends. The benefits and necessity of play for optimal child development are better known today than at any other time period

in the history of the world; yet play, all kinds, is not valued as important or as a right of the child. School officials, governmental policy makers, teachers, and parents need to understand that the role of play in a child’s life is critical. Based on research that play is an important predictor of school and civic success, some early childhood experts recommend that parents and teachers provide time for at least 30 to 40 minutes of intentional play in the home and/or classroom daily and an additional 30 to 45 minutes of play outside daily.

PLAY AND EARLY CHILDHOOD EDUCATION

Play is perhaps the roomiest area of early childhood education (ECE) in terms of researchers’ interest. Play, policies, and practices is the largest special interest forum of the National Association for the Education of Young Children (NAEYC). The topic is included in some way in practically every issue of journals and magazines devoted to young children; and many books have been published with the word *play* in the title. These works have been theoretical and research focused as well as practical and policy leaning in nature. If anything, the field’s interest in play is increasing.

Hardly a week goes by without yet another publication of a new book on the subject, or an announcement of a major forthcoming convention or community event centered on children's play.

Textbooks for teacher preparation courses dealing with play and ECE first appeared in the United States in the late 1980s with the publications of *Play and Early Childhood Development* by James E. Johnson, James F. Christie, and Thomas D. Yawkey and *Play as a Medium for Learning and Development*, edited by Doris Bergen. Many others have followed signaling sustained demand for syntheses of knowledge about applying research and theory on play to classrooms and other early childhood settings.

Over the last three decades advancements have been made based on research and theory with respect to what is known about play and various aspects of child development and early learning and in how to integrate and utilize this knowledge in ECE. Concepts and uses of play in early education cross over numerous topics including the ones that follow.

Theories

Why is play so important in ECE? Play finds itself center stage in conversations about early education due to common understanding of children by those who are with them on a daily basis. Parents and teachers know that play is a major occupation of young children, a way of their being in the world that rivals in importance their feeling loved and secure, cared for, and protected. Often heard are the expressions "Play is the business of childhood," "Play is the child's work," and "Play is the way children learn everything we can't teach them."

Many theories exist extolling the virtues of play in childhood and expounding upon its significance in early development and learning. These theories seek to explain play phenomena and what roles play serves in the life and growth of children. Teacher educators and teachers in early education learn and use play theories in multiple ways to guide their thinking and actions. These theories, which may be grouped as classical, modern, and

postmodern, have helped them form their own ideas and working theories about play in ECE.

Classical theories date from the 18th and 19th centuries and include surplus energy, recreation, and practice theories, associated with Friedrich von Schiller and Herbert Spencer, Moritz Lazarus, and Karl Groos, respectively. Teachers and parents can find value in all these theories. For example, viewing the purpose of play as being to expend surplus energy suggests alternating periods of active play with sedentary activities; the practice lens is applied by encouraging children to engage in play related to skills needed in later life, such as literacy-based dramatic play; and the play as recreation model implies the need for playtimes to offset and restore energy expended in intellectually challenging academic activities.

Modern theories date within the 20th century and include psychodynamic (Sigmund Freud and Erik Erikson), social learning (Albert Bandura), and the views of Jean Piaget and Lev Vygotsky. These perspectives are useful additions to classical accounts by helping to explain play as important for the overall well-being and development of young children. Foregrounding feelings and unmet needs, the psychodynamic lens suggests the importance of finding ways to have play themes that allow children to vent frustrations and work through conflicts associated with negative experiences.

Social learning theory is applied when modeling is used to enrich and extend play. Piaget's theory of play and assimilation gives a greater appreciation for the rhythm of learning cycles and the need for play as a period of consolidation. Applicative aspects of Vygotsky include employing facilitation strategies leading to richer play valued as a leading activity for children's mental development up to 6 years old.

Postmodern theories include sociocultural, critical, and chaos ones. Sociocultural theory can remind teachers to include culturally diverse content when setting up activities and to remain ever mindful of divergent values and beliefs. A critical educational lens brings up the politics of play as seen when academic mandates infringe on play demanding teacher attention, or when teachers are alert to the need to intervene or challenge children's play that is

stereotypic or exclusionary (social justice). Chaos theory with its emphasis on complexity, dynamic states, and nonlinearity recommends greater tolerance for ambiguity and the need for flexibility and adaptability. Play can be used to foster creativity and readiness for change, or “protean selves.”

Research Base

Empirical evidence complements the theoretical evidence for play’s importance in early childhood. In addition to experience and teacher and family lore, scientifically valid information comes from qualitative and quantitative disciplined inquiry (Johnson, Sevimli-Celik, & Al-Mansour, 2013). The evidence points to play’s value in early childhood development and well-being across a number of domains, including the personal–social and the intellectual–academic.

Vivian Paley’s legacy as an ECE teacher, researcher, and writer is well known and has yielded rich data across her many books and vignettes in support of how important play is to the emotional state of the child transitioning from home to school, a critical concern in ECE. Play is central to an ECE curriculum of caring and meaning so critical for helping “little children” become “little students.” Paley’s stories and anecdotes show how play used well by teachers produces classrooms where activities for constructing meaning occur along with the process of community building in which each child can feel a sense of comfort and belongingness as opposed to an anxiety about having to fit in and perform.

Another fruitful avenue of research targets self-regulation. Research done within the Vygotskian tradition with the Tools of the Mind curriculum, among other studies, has produced results supporting a relationship between mature role play and self-regulation. These studies estimate the young child’s ability to inhibit responding as evinced, for instance, in Simon Says game performance. Those showing greater inhibitory control on tasks such as this exhibit more high-level play. Cleanup time behavior relates to how well children engage in sociodramatic play.

Many studies using correlational and quasi-experimental methods in the 1970s and afterward have produced findings linking play with emerging numeracy and literacy and other indicators of cognitive and language development. Among the child abilities associated with play include math and spatial thinking, vocabulary, language use, narrative competence, perspective taking (including theory of mind performance), problem-solving skill, conservation ability, and divergent thinking.

Many criticisms have been made about this research corpus because studies have been beset by methodological flaws such as testers not being blind to play treatment groups in quasi-experimental research, or play not being defined well and conflated with other variables such as adult attention and peer interaction. Benefits might ensue from these variables and not play *per se*. Nonetheless, sufficient reason exists, due to the massed data coming from so many different sources, to dismiss the critics who might insist that these favorable results are spurious and due merely to the “play ethos,” or the biased general view or sentiment in favor of play being good for development. Still, more and better empirical work is called for on this important topic in ECE.

Types of Play

Given the enormous diversity of play manifestations, ECE delimits and defines certain kinds of play as falling within its scope and purpose. The major forms include solitary, parallel, and interactive to denote the level of social commerce, and functional, constructive, dramatic, and games with rules to indicate the cognitive forms of play. Usually these are nested. For example, a child putting a puzzle together is solitary-constructive play; two children side by side pushing cars along a wooden track would be parallel-functional play; but building a network of roads and bridges is constructive-interactive play. Pretense or dramatic play also is exhibited with varying degrees of sociality, such as solo puppet play, using puppets in close proximity with another child without interacting

(parallel play characteristic), or planning and staging a puppet show as a group.

The structural scheme just described is not all-inclusive since other forms of play involving one's body (physical activity such as simple motor movement or gymnastics) are left out—unless one considers this use of the body to be like the use of any other object, in which case the labels *functional* or *constructive* are useful. The scheme is elastic and can be stretched to include many forms of activity in ECE, even the use of books, DVDs, or computer games, as constructive or functional depending on the degree of order, planning, and goal directedness in the behaviors exhibited. However, ECE has typically employed other labels for such play, such as *reception play* (physically passive but mentally active play, such as listening to an audio-recorded story).

Additional types of play in ECE include risk taking, large and small motor, rough-and-tumble, sensory or exploratory, mastery, superhero or war, imaginative, imaginary companion, creative, computer or digital, language, art based, and academic play. These descriptive labels seek to convey something more about the play than simply reducing it to a choice along the cognitive form dimension from functional through constructive and dramatic to games-with-rules play. They can be used along with a consideration of the social level of the play (e.g., solitary, parallel, and interactive).

All these types of play in ECE are forms of *educational play*. Educational play is play that is on some level initiated, monitored, paced, and terminated by the teacher. Usually, it is seen in preschool, kindergarten, and primary classrooms, although it can occur in other indoor spaces such as gymnasiums and outdoor play environments. Teachers use materials, time, spaces, and their own energy in interaction with children's engagement with objects, symbols, peers, and their own bodies to create educational play at school. Educational play results from transaction between teacher and peer cultures, a blending of their different agendas motivated *relationally*. Such play is different from ordinary play children do in other settings, which is *intrinsically* motivated.

Educational play excludes certain kinds of behaviors that may be seen at school, such as illicit or deviant play or children doing pranks or other acts of playful misbehavior.

Play at school during recess for older children in the primary grades is usually considered recreational play and not educational play; although what happens on the playground does often have important social learning value. It can be relevant to the school curriculum. With younger children on the playground, teachers' presence and supervision and interventions are more prevalent and hence the play becomes a mix of recreational play and educational play. Whether recreational or educational in nature, play is important in ECE settings and is the business of the educators. They have important roles to play.

Teacher Roles

The role of teachers in children's play includes (a) play observation, assessment, and documentation; (b) communication; (c) making provisions; and (d) advocacy.

Observation, Assessment, and Documentation

Knowing and observing the broad types of play listed earlier and attending carefully to what children do while playing is the foundation for all other teacher roles. Children's play scenarios are rich and usually include more than one type of play, with the play constantly shifting. Teacher sensitivity is key to assessing play, assisting children with their play, and performing many other teacher roles. For example, teachers perform mediation when peer conflicts happen during play; and they are engaging in another kind of role by recording children playing for later discussion and teaching or curricular planning (*teacher-as-scribe*).

Preliminary to effectively observing play and using play observations in the execution of other important teacher roles is knowing the distinction between play frame and play script, or the play context and the play text within a play episode.

The frame or context surrounds the play but is not the play itself, and the play script or text is the play. For example, the former consists of preparations and negotiations and midstream adjustments, and the latter includes the enactments and thoughts emanating from being in states of play. This conceptual distinction clarifies play by setting it apart from other important processes and thereby helps in guiding interventions.

Teachers can help children return to their actual playing by stepping back as soon as possible after assisting with peer mediation or play suggestions, or after making an on-the-spot alteration in play scenery or prop availability. Teachers respect child-initiated play by not interrupting it with unnecessary teaching that snaps the play frame with some reality intrusion. Usually teaching can wait until later after the children are done playing. Sensitive teachers are keen on giving voice and empowering children at play. Interpreting play properly requires that it be viewed at both levels: the play context and the play text.

Although generally parallel-functional play is less mature and expected to be an earlier occurring form than dramatic and constructive-interactive play, within each type there are levels of performance. Teachers need assessment criteria to make judgments about play quality to monitor children's progress, to plan for new activities and learning opportunities, and to guide selections about what to include in children's work- and play-sampling portfolios, albums, classroom websites, or on classroom documentation panels.

Criteria used depend on chronological and psychological age and the kind of play under consideration. Generally, motor-physical, social-moral, language, cognitive, and imaginative-creative action dimensions are used when evaluating play. Play that is more developed typically possesses higher levels of differentiation or specificity of parts, as well as greater organizational coordination, coherence, or integration with respect to object and symbol use, verbal behavior, and social interaction. For example, mature social pretense is marked by an absence of conflicts over toys, persistence over time, and degrees of verbal social

interactions, symbolization, and transformational thinking (e.g., employment of invented or substitute objects over realistic props).

Play assessments of individual or groups of children over time provide valuable information about the progress occurring in the classroom provided that a consistent, comprehensive, and objective system is used. Drawings, constructions, story narrations, sociodramatic play, dance or musical performances, and the like can be captured on video, digital camera, and narrative descriptions, checklists, and records. Play observations are dated, retained, and organized for later study that can reveal insight about learning and development over time. These data serve accountability purposes well to the extent that procedures were used to avoid cherry-picking best examples only or otherwise misrepresenting the data. A fair and balanced account of changes in children's play preferences and abilities over time is required in order that play assessments and documentation be considered a sound alternative to more formalized data such as testing results.

Play documentation is valuable for public display and communication with parents, other teachers, and school administrators. Documentation has different forms, including panels, class albums, books or e-books, slide shows, movies, and other creative products. Documentation of play must include process and purpose and not just finished products. This can be achieved by including concrete examples of a child's play/work at progressive levels of completion or photos or video clips revealing progress. Documentation should not be haphazard or random. Care should be taken to tell a story or to make an explanation of the play/work unfolding and put on display. Written commentary by adults is useful to explain the child items; transcriptions of child talk made while the items were being produced are very informative. Documentation and play assessment are handy to convey topics of learning in a classroom, show developmental progress, show accountability, and make learning and playing visible. They can extend playing and learning in the present and future as well

by the memories and inspirations provoked by the records and displays.

Communication

Many teacher roles connected with children's play in ECE have to do with communication. This was alluded to earlier when distinguishing play frames and scripts and sensitive teacher interventions. The degree of teacher involvement in play deemed necessary or helpful to children is a critical question. Generally speaking, the contingency principle is used to answer this question. Teacher play facilitation strategies are employed less or are less directive in nature as children show more independent competent play, and are more frequent and teacher directive when children seem less able or successful in play. For example, teachers may see children needing help to complete making a bead necklace.

To illustrate further, Smilansky (1968) discussed two kinds of interventions using sociodramatic play with preschoolers. Outside interventions (external to the play episode) were when teachers provided background experiences related to the play theme, such as taking the children on a field trip to the grocery store. The teachers set up special props and play areas to support the grocery theme. Inside interventions (internal to the play episode) refer to the use of teacher strategies to scaffold children's enactments. As mentioned, teacher observation is important to discern how to support and scaffold play. At times, teachers' parallel playing is enough to encourage children to play; at other times, teachers can coplay with the children to provide more structure, or offer hints to advance play plots. Sometimes they tutor play by directing the play episode, for example feeding the children lines to say for enacting a character in a story dramatization (*thematic fantasy play*).

Scaffolding is done dynamically in accordance with the child's level of performance. Educational play is understood as relationally rather than intrinsically motivated. Children are motivated to play in relationships with teachers. Adult involvement in children's play is justified when children

can exhibit improved play skills with peers later on, independent of teachers' presence. Children receive play ideas and actions from teachers. This enriches and expands their play repertoires that can be put to use on other occasions involving peers only.

The communication role is enacted across many play settings, ranging from children in so-called free play periods to when teachers are facilitating or directing their play in large or small groups or on a single-child tutorial basis. Teachers' use of questions, helpful comments, suggestions, and showing examples are all modes of influence on children's play. Communications across the daily schedule have direct or indirect effects on play, such as seen when a special visitor during community time inspires a certain theme of make-believe play during the designated play periods of the school day.

Making Provisions

Making provisions in outdoor and classroom environments is an important teacher's role enacted in setting up permanent and semipermanent features as well as temporary situational arrangements for specific theme-based or special event play. Space and materials as well as time allotment are factors that enter into the equation for quality play.

Space and objects are arranged in various play centers that are typically thematically defined and labeled as the book or block area, writing center, art center, dramatic play center, music center, and so forth. Areas with ECE classrooms are designed to promote specific activity either with or without the participation of other children or the teachers. The quality of play depends in part on how well the centers are organized internally and in relation to each other over the floor plan of the room. For example, centers likely to elicit more quiet play, such as in the book or small manipulative objects areas, should be located some distance from the large-motor, blocks, or dramatic play areas.

Borders and partitions help define play centers, with bulletin boards, bookshelves, and other materials helping to divide indoor space. Play is

supported and can be enhanced when partitions are used within an open-plan design. Dividing on two or three sides but open and accessible on at least one side supports quality play. Lofts and other sheltered areas for private and cozy play are also conducive to positive indoor play. Further recommended is striving for a balance of types of play materials, such as complex versus simple and open-ended and closed-ended. Such balance affords better quantity and quality of play and variation of child uses of different materials in the environment. Consideration also needs to be given to the degree of realism versus symbolic abstraction in the materials, and to how many children can engage with the materials at a given time and place (Johnson et al., 2005).

Moreover, it is important to balance technological and other objects. Teachers should plan to assure that children are challenged proportionately with physical materials such as three-dimensional blocks and computer-based materials such as electronic block building programs. In general teachers' criteria in making situational arrangements for play involve balance and variety of types of play opportunities, with special attention given to promoting collaboration, language use, and creative expression. Toys should be chosen that stimulate many forms of play, conducive to problem solving, socializing, and creativity. Always important is the safety and the developmental appropriateness of the materials and the play environment design.

Time and scheduling for play is important. Play experiences must be planned in relation to other curriculum activities and parts of the daily schedule (Johnson et al., 2005). The beginning and ending of the school day for play can compromise quality since children can be arriving and departing at different times, which can disrupt play in social groups. Younger children may need an hour at least in order for higher quality play to emerge and stabilize. Some children spend a great deal of time planning and getting set up for play. Play periods that are too short preclude high-quality play. In addition, the tempo and pattern of different activities across the daily schedule are important to

consider—for example, more active times being broken up with more quiet times, such as free play and circle or community time, with snack and nap time. Free play or child-initiated activity is interspersed with teacher-led activities and small groups. The entire school day must be considered when evaluating the play potential of an ECE program since there can be interactive effects among the different activities that are scheduled. For example, what happens during the structured teaching parts of the curriculum can benefit play, as when a unit on the sea stimulates sociodramatic play involving content related to sea life.

Making provisions entails space and time considerations and the selection of toys and materials. The building blocks are numerous features and the glue that holds it together is the way that teachers enact their roles in the service of playing and learning children. Various roles to support children at play are common across ECE programs, but they can demand particular expression and take on special meaning in certain cases when ECE classrooms are operating with different philosophies and within different cultural contexts. Teacher performance makes a difference to how well children play during the early years.

Advocacy

Advocacy in ECE has been defined as championing a cause, amplifying voices, and seeking and making changes in the lives of young children and their parents and teachers. Play advocacy is central in mission statements of major professional organizations such as the Play, Policy, and Practice Interest Forum of NAEYC, International Play Association, International Council for Children's Play, and Alliance for Childhood. Professionalism in ECE includes play advocacy.

Children have a basic right to their childhood, and play and childhood go together. Remarkably and sadly, often play potential is held back by barriers or through lack of play affordances. Teachers and even parents do not always understand or respect or value the importance of play. Many are indifferent or ambivalent, caught

between conflicting beliefs or goals for children's well-rounded development and school success.

Childhood compression or the societal push to rush children through their immaturity poses a serious threat to fulfilling the promises of play during the early years. Anti-play tendencies are apparent in many school systems in the United States and in families where parents pressure children with demands for academic excellence and push them toward adult-defined group activities such as taking lessons, joining clubs and organizations, ball leagues, and the like. This adult overmanagement of children's lives can lead to more passive, less robust play. Play is sharply curtailed when schools drop recess or neglect to provide opportunities for curriculum play.

The ever-increasing commercialization of childhood also raises concerns about play. Market forces have an effect on schools and families through media and advertisement and when coupled with peer group and popular culture influences can erode teacher and parental judgments and authority. Young children can be easily swayed by TV commercials to desire products that are not conducive to quality play. Materialism and a desire to conform can interfere with wholesome recreational and educational play.

Teachers and parents can work together to ensure that all children play in a variety of ways and that they keep getting better as players. Frost (2010) champions and informs about providing play-enhancing environments such as state-of-the-art playgrounds. He recommends favorable, socially inclusive environments for all children that honor the right of each individual child to play. Frost opines that priority needs to be given to balancing nature and outside play with technology-related pastimes and recreation. He further states that more open-framework intergenerational play is needed that strengthens social bonding and creativity.

Changing the curriculum toward more play-oriented experiences in classrooms is another step in the right direction. For example, prekindergartens and kindergartens need to have times allotted for child-initiated and teacher-facilitated play.

Teacher-directed play activities also have a place, such as in creative dramatics activities, art projects, and music and dance performances. Primary grades are times for playful learning through educational games, simulations, projects, and investigations. Recess and playground time are extensions of such sound, child-sensitive, activity-based educational programs.

As parents and teachers gain more insight into the importance of play, and understand how adults are often implicated in threats to play, barriers that now exist may begin to come down and play can flourish for young children. Play advocacy by ECE professionals, parents, and other family members can be an important catalyst and a key to success.

Advocacy can be expressed in various ways. Researching the topic, collecting resources on the importance of play for all children, and informing oneself are first steps. Research can include observing children play; talking with them about play to gain their perspectives; taking inventory of play opportunities already existing in schools, communities, and homes; and assessing play needs and interests with other teachers, administrators, and parents and community leaders. What are or can be play areas, activities, or events? Information should be organized, synthesized, and discussed leading to position papers and action plans. Advocacy groups such as Alliance for Childhood and Defending the Early Years urge lobbying for better play, writing to policy makers as well as to editors of newspapers and magazines, hosting a play day at school or a play community event, and joining or donating to professional organizations that advocate for play.

Play and Individual Differences

Within ECE much has been said about the importance of developmentally appropriate practices (DAP). DAP is an inclusive notion that takes into account not only developmental level or psychological age but also the cultural background of the child as well as other so-called individual difference variables.

Systematic individual differences exist in the expression of play across ages and cultures of children and due to children's gender, personality, and special needs. For instance, boys are more likely to engage in rough-and-tumble play, superhero dramatic play, large-block play, and play themes that are active or adventuresome with pretend violence or aggression. Girls typically prefer to play in smaller groups and show an interest in a greater variety of toys and play materials, including constructive play and other table activities.

Differences in play reflect not only age and gender but also personality. Some children prefer more reality-oriented play such as building models, doing puzzles, or reading realistic stories, while other children prefer more fantasy-oriented activity, as seen in their choice of toys, games, books, and dramatic play themes. Others are more object centered than person centered in their play. The former tend to pay more attention to the stimulus detail of play objects; the latter are more concerned with peer group reactions, adult attention, and social interaction.

Different kinds of abilities and exceptionalities have an impact on play development and expression during the early years. To be sure, all children have similar interests and needs for play and peer relations, but some children who have special needs possess a more limited repertoire of skills needed for elaborative forms of independent and group play. This can influence the rate of development for children and affect play. Some children may require supports for certain kinds of play.

Socioeconomic status (SES) and cultural differences are also contributors to play. SES factors, such as low income or poverty, may set limits on availability and accessibility of high-quality play environments and expensive toys and equipment. Quality of play may suffer as a consequence. Lower levels of play may be seen more often than higher forms of play when children lack experience with basic play materials, adult modeling, or encouragement.

Children live within vibrant cultures. Cultural factors interact with SES and individual difference

variables to produce variation in play behavior and development during the early years. Although structural features of play such as sociality of play, elaboration of language, and imagination may not differ from culture to culture, play themes and content are often culturally specific. Educational or academic play, and other kinds of specific play types such as digital play, may show higher degrees of similarity across developed and developing countries than do recreational play with games, books, sports, or dramatic play themes, which are more likely to retain the unique flavor of specific individual cultures. Nowadays life is global; play is global, but also very local and personal, and important in ECE. The way play is done must be developmentally appropriate but also set to individual differences and the social and cultural situation of the child.

PLAY AND EARLY WRITING

Play and early writing refers to a practice in early childhood education in which play and writing practices are combined in a manner to enhance early writing and literacy development. There is convergent research evidence that (a) young children produce meaningful representations of their knowledge, thoughts, and emotions through their writings and drawings and (b) writing during play promotes children's reading, writing, language, and cognitive development. There is also convergent evidence that writing is underutilized in pre-kindergarten and kindergarten. When given opportunities to write during play, children explore oral and written language, apply what they learn about reading and writing, and engage in authentic writing experiences. This entry first explores what constitutes writing in the early childhood context and suggests ways in which educators can support very young learners by providing them with effective learning environments and tools conducive to the exploration of the written word. The entry then discusses how teachers can take advantage of children's interests and prior knowledge and use peer and teacher scaffolds to encourage effective writing.

Definitions and Types of Writing in Early Childhood Education

As in other contexts, young children's early writing during play takes on many forms. The following definitions of writing proposed by Phyllis Neves and Stuart Reifel (2010) provide particularly good characterizations:

Scribbling: Random marks combined with speech/gesture that do not represent or denote a pictograph, ideograph, or writing.

Scribble-writing: Scribbling combined with speech/gesture that indicates "writing": simple letters or conventional adult writing.

Pictograph: A drawing combined with speech/gesture that denotes a person, object or gesture

known but not necessarily seen. Several drawings can be on one page. Generally, the child orally labels the drawing or parts of the drawing. This category includes scribbling/pictographs.

Ideograph: A drawing combined with speech/gesture that tells a narrative or that represents an idea or a relationship. This category includes scribbling/pictographs.

Symbolic drawing: A drawing combined with speech/gesture that directly denotes what is seen by the child—that is, the child does not see the drawing as a representation, but as a similar object.

Letter writing: Individual letters or strings of letters that combined with the child's speech indicate they do not represent words.

Invented spelling: Individual letters or strings of letters that combined with the child's speech/gesture indicate that they represent words. (p. 153)

Conventional writing is often a part of early writing, especially with name writing. As students progress through the primary grades, they spell conventionally, especially words included in spelling instruction.

Environmental Supports for Early Writing

Environmental supports for writing include purposeful efforts that increase the quantity, and often the quality, of young children's writing. Common practices include providing the space, materials, and technologies that encourage writing. When considering space, teachers take into account the need for children to have ample space to write. For example, an environment that provides uncluttered tables, appropriate-size chairs, and easy access to materials enables children to work independently as well as interact with peers and teachers as they write. This environment also addresses the special needs of young children as they regulate their bodies and develop fine motor control to write.

Writing environments designed to enhance children's writing also provide environmental supports, including necessary writing supplies (e.g., paper,

pencils, markers, and dry-erase boards) that children can easily reach and put away. Classroom environments that support writing may include designated amply supplied writing centers or writing carts that can be used in conjunction with other play activities. Teachers may also, for example, provide menus and tablets for taking orders in a classroom restaurant center, add a table for note taking in the library center, and provide a classroom mailbox so that children can write messages to each other. In addition, a variety of print materials that serve as models and sources of ideas are available for children as they play. These materials may include children's literature, word walls, posters, and other children's writing. Various technologies also support children as they write and play. For example, iPads might be used to create drawings and stories, record observations and events, take photos of children's creations, and enable children to pretend they are doing a variety of jobs. Well-placed computers allow children to look up information, write stories, and pretend to work. Low- and high-tech assistive technology is needed to support writing for children with disabilities.

Children's Interests and Prior Knowledge

Children's interests and prior knowledge influence the quality and content of children's writing. Therefore, supportive writing environments take into account children's experiences, and teachers recognize that all children's contexts (e.g., school, home, and community) provide prior knowledge for writing. Teachers are aware that inclusion of children's interests and prior knowledge impacts children's sustained attention to early writing. They also know that ample opportunity for peer interaction in activities that support writing provides development and elaboration of children's interests in writing as peers provide support for each other's writing interests.

School practices noted in research include the inclusion of specific content areas, such as the arts, math, and science, in addition to literacy-specific activities, such as book reading and reading

responses. Teachers also include experiences, such as field trips, nature walks, assembly programs, and indoor and outdoor play, to utilize children's interests and prior knowledge to promote children's writing. Classroom planning, for example, through thematic and project-based learning, integrates children's interests and prior knowledge and provides the context for new interests and knowledge. As children insert their own interests and intentions into their writing, they record their observations, take notes to remember, express thoughts and ideas, respond to materials read and content learned, and create stories or note information to share with others. For example, they represent the savannah studied in their combined drawing and writing, write about the three little pigs, and produce ideographs of powerful thoughts such as a butterfly saving a girl from an evil bird.

Home experiences similarly include children's experiences that can be incorporated into children's writing. Teachers can encourage children to model their writing on writing they see at home, including grocery lists, notes, and letters. For example, immigrant families provide rich sources of information for their children as they write letters or e-mails to family members in their home country. Teachers can also provide opportunities for children to use family-based information, such as a child's pet or activities with siblings, to promote writing. Drawing upon children's interests and prior knowledge in this way not only provides children with models of writing but also emphasizes the importance of writing in their day-to-day lives.

Teachers' Scaffolding of Early Writing in Play

Teachers' scaffolding of early writing in play is central to increasing the quality of young children's writing. Teachers support children's understanding of writing and writing practice through providing appropriate environments, building content knowledge, fostering children's interests, and drawing upon prior experiences as noted in the previous two sections. But these are not

enough. Teachers' positive and supportive interactions with children as they engage in opportunities to write over time are essential for promoting young children's writing. Teachers' interactions with children and the experiences they provide are guided by teachers' understanding of young children's writing and influenced by their teaching practices.

Teacher interactions in play and early writing are recursive. They take children from mark making to conventional writing and complex symbolic representation, and from vague single messages to multimeaning composition with conventional writing and drawing. These interactions often take the form of teacher-child shared responsibility for the learning rather than being solely teacher controlled or child controlled. Through teachers' verbal and nonverbal communication, young children learn what it means to be a writer. The interactions give indicators of the functions of talk in writing, for example, describing intentions, explaining, and extending child's conversations (e.g., conversational oil such as "OK" in dialogue communicates that one has heard the speaker and is encouraging him or her to say more). Teachers ask children questions about the meaning of their writing and address many aspects of writing, often within the same writing event. They address children writing to express or communicate (e.g., a thank-you note to a friend, a book reading response), to develop handwriting (e.g., fine motor development), writing conventions (e.g., alphabetic code, sentence mechanics), and authoring processes (e.g., understanding audience, revising).

Conclusion

The environment, children's own interests and prior knowledge, and social supports (adult and peers) provide rich educational opportunities for young children to write. Play provides a context for rich enactment of these opportunities as children interact with writing materials and technologies, their peers, and their teachers to develop their handwriting and drawing, explore writing conventions, experiment with authoring processes,

and communicate with themselves (e.g., note-taking) and others (e.g., writing stories and sharing past experiences). Teachers play an important role in this process as they set up classroom environments that support play that takes into account children's interests and prior knowledge and as they scaffold children's learning through play.

PLAYGROUND STRUCTURES

Playground structures can be broadly defined to include both fixed and portable structures included within an area designated for outdoor play. Many types of playground structures exist and vary in quality and purpose. Generally, playground structures afford children a specific physical or sensory experience. Typical playground structures allow

children to practice and demonstrate their abilities to slide, climb, swing, jump, and balance. Playgrounds and the structures found therein have changed dramatically over time to reduce injuries and to mitigate apprehension about liability for injuries. Recent innovations in playground design emphasize the benefits of more flexible manufactured and natural landscape structures that allow children to engage in more diverse types of play and to experience even appropriate degrees of risk. In this entry, readers will find a brief history of playground structures, a discussion of challenges to provide safe play that meets children's developmental needs, and a description of suggested features for playground structures.

History

The first playground structures were rotating rope swings atop tall poles. Children could run around the pole, jump, and then, using the force they accumulated, swing around the pole for a few seconds. From such minimal beginnings, manufactured equipment such as steel slides, jungle gyms, seesaws, swing sets, and other equipment emerged—often installed directly into the ground or even on asphalt. Because injuries naturally resulted, safety concerns spawned new regulations, design standards, and even the elimination of some traditional types of playground equipment. Over time and with the development of national safety guidelines, standardized manufactured structures, from single pieces to elaborate, integrated structures, have become commonplace in a multitude of indoor and outdoor play spaces.

Safety and Risk

Research suggests that homes, motor vehicles, firearms, and disease are much greater risks to children than are school play yards. However, maintaining safe play structures remains central to quality early education. Studies indicate that most severe injuries of children while attending preschool result from falls from play structures. Given the necessity of high safety standards, some child development experts suggest that failing to

respect children's inherent need to explore risk may indeed cause some injuries to result as children seek challenge in physically limited "safe" environments. The benefits associated with children's risky play continue to be debated. Although the research related to these issues is emerging, some positions claim that some risky play is essential for healthy child development. At present, playground designers are encouraged to widen the range of play choices considering children's need to test their limits. Landscape and equipment features along with temporary supervised affordances permit children to safely experiment with climbing to new heights, pushing themselves to higher speeds, and encountering "dangerous" things such as certain sharp tools and water.

Suggested Features

Although this entry has included the topic of playground safety, individuals must consult all appropriate regulations for a thorough description of requirements for outdoor play structures. Fall zones, equipment spacing, resilient surfacing, and entanglement, as well as entrapment, pinching, and protrusion hazards, are a small sample of considerations within most guidelines. In addition, some equipment (e.g., trampolines, rope swings, overhead rings, certain spiral slides) is designated *not appropriate* for any age group. A program's responsibilities to provide documentation of inspections and maintenance are also outlined in regulations and guidelines.

Within established specifications, experts recommend including a wide variety and sufficient number of age-appropriate features that are accessible to those at all ability levels. Research suggests that many manufactured fixed structures afford only limited types of play. Conversely, natural features provide physical, constructive, dramatic, and exploratory play behaviors. Embankment slides, climbing structures (including rock climbing walls or natural climbing features such as boulders and hills), balance beams, and age-appropriate swings are staples in many of today's excellent playgrounds. Multipurpose wooden decks can provide physical challenges when constructed at gradual

heights and can be transformed by children into settings for pretend play. Paved pathways facilitate the use of tricycles and other wheeled toys. Gender-neutral playhouse structures can be portable and are a staple for sociodramatic play by all children. Natural boundaries designed to enclose and highlight work with sand, water, or mud supply unending developmental value and pleasure to children. When designing a diverse environment to support active, "deep," and engaging play, structures for the storage of loose parts, toys, music, art, and construction materials are paramount.

Benefits of Playgrounds

Intensified recognition of the role of physical activity in combating children's health crises has revealed a nationwide disparity of safe, interesting, appealing, and accessible play options. Fortunately, new playground initiatives and innovations fuel a growing imagination for play structures that strengthen bodies, instill confidence, and honor cooperation within schools and communities.

POLICY AND EARLY CHILDHOOD EDUCATION

In the United States, the government shares in the responsibility of ensuring that children are healthy, safe, and educated through the implementation of laws, regulations, and investments. Although public policies governing the rearing and education of older children have a long history, the last half-century has seen an increased focus on policies directed at children prior to formal school entry. This shift has stemmed from two major historical developments. First, there has been an increase in the number of young children needing care while their primary caregivers work. Second, there has been an increase in knowledge about child development and the importance of early enriching experiences for later learning. These two major developments have resulted in an early childhood education (ECE) landscape that now includes a diverse array of policies and services from birth to age 5 (e.g., child care, home visiting, prekindergarten programs).

After providing a brief historical overview of ECE policy in the United States, this entry describes current major federal and state ECE policies, starting first with those policies focused

on children birth to age 3, followed by those focused on children ages 3 to 5. It concludes with a discussion of policies aiming to connect and align ECE systems with K–12 school systems.

Historical Context of ECE Policy

The earliest records of schools for very young children in the United States date back to the Industrial Revolution in the 1800s, when churches and charitable organizations began operating “infant schools.” The purpose of these schools, which served children ages 18 months to 4 years, was to provide child care for parents newly working in factories. Although these schools were not sponsored by the government and faded out by the 1860s, they were an early example of child care options commencing to support parental employment. The next time that child care surfaced to support parental employment wouldn’t come again until 1940, when the federal government became involved for the first time in child care in a substantial way through the passage of the Lanham Act. Funds provided under the Lanham Act were used beginning in 1943 to fund a network of child care centers in response to the increased demand for women’s labor to support the defense industry during World War II. Unlike the Industrial Revolution, the responsibility of war fell on the government. However, when the war ended, so did the funding from the Lanham Act, and most of the child care centers were closed.

During those same years, there were also great advances in our understanding of child development. Scholars such as Arnold Gessell and Urie Bronfenbrenner were pioneers of studying typical and atypical development of young children and making connections to children’s education. University-based lab schools, such as the Ruggles Street Nursery (now known as Tufts Eliot-Pearson Children’s School) and the Yale Child Study Center, served the dual purposes of studying best educational practices for young children and providing care. Knowledge about

the potential benefits of preschool education fueled the nursery school movement, in which more affluent parents enrolled their children in privately run nursery schools. As described by scholars Edward Zigler and Sally Styfco, this movement was an important predecessor to the next major federal ECE initiative: Head Start. Head Start was enacted in 1965 to provide preschool and other services to economically disadvantaged children as part of President Lyndon Johnson's War on Poverty. The passage of Head Start marked the first investment by the federal government in an early childhood program focused on increasing children's school readiness and healthy development as opposed to being focused on supporting parental employment. Today, Head Start continues to serve low-income 3- to 5-year-old children and their families, as discussed further in the section on ECE policies for children ages 3 to 5.

By 1970, beliefs about the importance of child development converged with the needs of working parents at the White House Conference on Children. That year, affordable high-quality child care programs were identified as the most urgent need of American families and their children. In response, the Comprehensive Child Development Act (CCDA) was written. Also known as the Mondale-Brademas bill, the CCDA would have created a voluntary, universal child care system. The bill's preamble described its goal as providing "every child with a fair and full opportunity to reach his full potential by establishing and expanding comprehensive child development programs and services" (California Newsreel, 2015, p. 26). Although the bill was passed by Congress with bipartisan support, it was vetoed by President Nixon. This bill has been described by scholars Zigler, Katherine Marsland, and Heather Lord as a "golden moment squandered" (Zigler, Marsland, & Lord, 2009, p. 13). The United States still lacks a comprehensive ECE system; however, a number of additional federal and state policies have since been implemented to support the education and development of young children from birth to age 5.

ECE Policies for Children Birth to 3

Early Head Start

Enacted by the federal government in 1995, Early Head Start is an extension of Head Start services to pregnant women, infants, and toddlers. Like Head Start, Early Head Start is a two-generation program well known for providing comprehensive services, including parent support, social services, mental health services (for both children and their families), and ECE. Early Head Start serves approximately 175,000 low-income children each year through 1,000 programs operating across the 50 states. There are four program options for Early Head Start: center-based services, home-based services, family child care services, and combination services. Each provider determines which program option to provide based on a needs assessment of the community. The center-based program option serves 46% of Head Start enrollees, provides services directly to children in an ECE setting, and offers home visits to enrolled families twice a year. The home-based program option serves 42% of enrollees and offers weekly home visits to each family that focus on supporting parents in promoting their children's development. The family child care program option, which serves a smaller percentage of enrollees, provides ECE to children in a familylike setting, typically in someone's home. Providers also have the option to offer a combination of both home- and center-based services.

To examine the benefits of Early Head Start, a national randomized controlled trial was authorized by the U.S. Department of Health and Human Services (HHS). The Early Head Start Research and Evaluation Project found that Early Head Start had small to moderate impacts on a wide range of child, parent, and family self-sufficiency outcomes at the end of the program. Impacts were the largest for programs that fully implemented Early Head Start's performance standards and for those that offered combination services. Although impacts on children's social-emotional outcomes, parenting, and parent well-being remained when children were 5 years

old (2 years after Early Head Start ends), those impacts were no longer detectable by the time children were in Grade 5.

Child Care Subsidies

The year after Early Head Start was enacted, the Child Care and Development Block Grant provided federal funding to expand child care subsidies for working parents. States were also required to match the federal funding. The goal of child care subsidies is to lessen the cost of child care for lower income working families while supporting parental choice. The current funding stream, known as the Child Care and Development Fund (CCDF), reduces qualifying parents' cost of care for children under the age of 13. In practice, approximately 1 in 3 children served by child care subsidies are under the age of 3.

Although states determine family eligibility criteria and the types of settings that qualify for subsidies, in general, subsidies can be used to pay for care in a variety of settings, including center-based care, family child care, or care in the family's home (e.g., from a relative). Benefits of this policy include that it increases family disposable income and parental employment, making it an effective work support policy. On the other hand, one of the biggest critiques of the child care subsidy policy is that many of the children end up in low-quality care that is known to have a negative impact on their development. There are several reasons why a family receiving child care subsidies may not choose high-quality care. Two widely cited reasons are that (1) high-quality care may not be available nearby and (2) local high-quality providers may choose not to accept subsidies. Some states have attempted to address these issues by increasing the value of subsidies or using a tiered reimbursement system, in which care settings with high-quality ratings receive a higher reimbursement rate for accepting subsidies. The idea is that such policies will both encourage high-quality care settings to accept subsidies and encourage low-quality settings to improve upon their quality.

Home Visiting

In addition to home-based Early Head Start, a number of other home visiting programs have received government funding in recent years to promote positive parenting practices and support children's cognitive, achievement, social-emotional, and health outcomes. Specifically, in 2010, Congress launched the Maternal, Infant, and Early Childhood Home Visiting Program (MIECHV), which allotted funding to states in order to provide evidence-based home visiting services to low-income families. In these programs, a professional or paraprofessional visits pregnant mothers or new parents in their homes to deliver information and engage in parent-child activities. These services are often combined with other services, such as health care and referrals. Home visiting has been seen as an especially useful service delivery mode for reaching isolated families and tailoring services to individual families' needs.

There are 17 home visiting programs that meet the HHS criteria for evidence-based models. These include Family Check-Up, Healthy Steps, and Parents as Teachers. The most widely known evidence-based home visiting program is the Nurse-Family Partnership (NFP). Developed by David Olds in the early 1970s, NFP now operates in more than 400 counties across the United States with a combination of public and private funding. In NFP, registered nurses visit first-time, low-income mothers weekly to biweekly in their homes starting early in pregnancy and ending when children are 2 years old. The program focuses on improving mothers' health, prenatal care, parenting skills, and economic self-sufficiency. Large-scale evaluations of NFP have found meaningful long-term impacts on a number of maternal and child outcomes, including reductions in child abuse and neglect, emergency room visits, and child behavior problems. The newest efforts for NFP include increasing program fidelity and continuing to improve its model and delivery.

In sum, though policies supporting the care and development of children birth to 3 are still in their infancy, great strides have been made in the past 2 decades as policy makers and the public have

increasingly viewed the first few years of life as foundational to all of the learning, health, and development that follows.

ECE Policies for Children 3 to 5

One of the most prominent ECE policy issues is the expansion of public preschool. According to a 2013 Society for Research in Child Development policy brief written by Hirokazu Yoshikawa and colleagues, 39% of 4-year-olds were then attending Head Start or public prekindergarten programs. As the merits of preschool education policy have been deliberated, both Head Start and state prekindergarten have been put under the microscope.

Head Start

Today, the federal Head Start program provides preschool services to about one million low-income children each year, reaching approximately half of those who are eligible. Like Early Head Start, Head Start has been subject to a rigorous national randomized controlled trial. The National Head Start Impact Study found that, at the end of the program, the group of children offered Head Start showed greater benefits in school readiness and measures of family processes than the group of children who were not offered Head Start. However, by the end of first grade, the groups looked similar. Given these findings, whether Head Start “works” has been the subject of much debate. Many hypotheses have been generated about why Head Start has not resulted in more long-term impacts on these outcomes. One explanation is that members of the control group ended up having similar experiences to those in the experimental groups, even though they were not offered Head Start as part of the experiment. In other words, children who weren’t enrolled in Head Start still had a high likelihood of receiving comparable services. For example, in the Head Start evaluation, nearly half of the control group enrolled in center-based care. It should also be noted that though there weren’t many average effects that persisted to first grade, some populations of children in Head Start did continue to show improve-

ments. Importantly, Head Start had more robust and longer-lasting impacts for dual language learners and children with special needs.

A different study of Head Start by David Deming found that even when test score impacts converge, there may be long-term impacts on other young adult outcomes. Deming compared siblings that differed in their enrollment in Head Start, controlling for a number of other differences between the siblings. He found that Head Start participation produced positive benefits on a number of young adult outcomes, including high school graduation, earnings, and reduced crime. The findings of this study and the National Head Start Impact Study highlight the complexities of trying to determine if a program works. The debates around Head Start research findings have brought an increasing recognition that to inform policy, it is important to ask not only if a program works, but also for whom, for what outcomes, and under what circumstances. The answers to those questions will inform not only the future of Head Start, but also the numerous other prekindergarten programs that are publicly funded.

State Prekindergarten Programs

Along with the federal Head Start program, a number of states have implemented their own prekindergarten programs. These programs are funded, controlled, and directed by the state governments and are distinct from state child subsidy programs (though in some cases the two programs are coordinated). According to the latest *The State of Preschool Report* from the National Institute for Early Education Research (NIEER), there are 53 programs operating in 40 states and Washington, D.C., that serve 1,347,072 children. These programs are quite diverse, varying on indices of both access and quality. Twenty-nine programs have an income requirement for enrollment (versus no income requirement), 15 programs require full-day operation (versus half-day or locally determined), and 39 programs operate on an academic year (versus locally determined). Though the overall quality of programs has increased in recent years, only five state programs (Alabama, Alaska, North

Carolina, Rhode Island, and Louisiana) meet all 10 benchmarks used by NIEER. The benchmarks include whether the program has comprehensive early learning standards; requires the lead teacher to have a bachelor's degree; requires specialized training in pre-K; requires the assistant teacher to have a Child Development Associate (CDA) credential; requires at least 15 hours a year of in-service training; has a class size of 20 or lower; has a staff-child ratio of 1 to 10 or better; has vision, hearing, and health support service; offers at least one meal; and conducts site visits. On the lower end of the spectrum, there are six states (California, Ohio, Vermont, Florida, Texas, and Pennsylvania) that meet fewer than half of those benchmarks.

Differences in access and quality across states can in part be explained by the different amounts of funding that are allotted to prekindergarten programs. In addition, even once state money is allotted to fund prekindergarten programs, difficult policy decisions must be made about how to spend that money. In a 2011 book titled *The Pre-K Debates*, edited by Zigler, Walter Gilliam, and Steve Barnett, scholars weigh in on current controversies, such as whether a program should be targeted (i.e., have an income requirement) or universal (be offered to everyone, regardless of income); what the minimum teacher requirements should be (e.g., Should a bachelor's degree be required?), and how program quality should be supported. Other policy issues surrounding prekindergarten programs include whether programs should be 1 year or 2 years; what curricula programs should be used; and whether the benefits of preschool justify the costs. Although the answers to these questions aren't yet clear, recent research has allowed for some recommendations based on the best of what we know.

The 2013 Society for Research in Child Development policy brief summarizes research finding that a second year of preschool shows additional benefits, but smaller benefits than from a typical year spent in a 1-year program. Yoshikawa and colleagues also argue that intensive curricula targeting specific skills (e.g., math, language, literacy) produce larger gains in those areas than

global curricula. Another conclusion is that the benefits of preschool outweigh the costs, but only if those programs are high quality. This conclusion comes from estimates from seminal high-quality programs, such as the Perry Preschool program, that have tracked program participants and their control group counterparts into adulthood and provided data on outcomes that provide savings to society, such as reduced special education placements, grade retention, and arrests. Benefit to cost ratio estimates for such demonstration programs have ranges from 2.5 to 1 to 7 to 1. Estimated benefit to cost ratios for more contemporary universal prekindergarten programs have ranged from 3 to 1 to 5 to 1. In short, "high-quality early childhood education programs are among the most cost-effective educational interventions and are likely to be profitable investments for society as a whole" (Yoshikawa et al., 2013, p. 13). This knowledge, combined with the fact that many state prekindergarten programs fail to meet quality benchmarks, begs the question of how to implement quality programs at scale. One potential policy solution is statewide quality rating and improvement systems (QRISs).

Quality Rating and Improvement Systems (QRISs)

The rapid development of QRISs was propelled by President Barack Obama's Race to the Top Early Learning Challenge, which awarded funds to select states beginning in 2011 to support early learning. A key goal of those awards was to support the creation of QRISs to evaluate and improve programs. QRISs also aim to create more transparency by providing families with information about programs' quality. Although QRISs began as a market-based approach, it has evolved to include increasing levels of professional development opportunities, such as coaching and mentoring. Today, over half of all states have QRISs in place. As QRISs expand, a critical policy issue is whether the tiered ratings typically used by QRISs predict children's learning, a necessary precursor to these systems' ability to improve quality. To date, findings have been

mixed. One study by Terri Sabol and colleagues found that highly rated programs produced children's learning outcomes that looked similar to outcomes produced by low-rated programs. On the other hand, studies from a special issue in *Early Childhood Research Quarterly* devoted to research on QRISs found that ratings predicted growth in literacy skills and some social-emotional outcomes. Given these inconclusive findings, some have cautioned that there are considerable issues with QRISs that need to be addressed before these systems can accomplish the stated goals.

Preschool Through 3rd Grade Continuum

Just as the QRIS movement has attempted to create continuity in quality across ECE programs, another movement—the PreK–3rd movement—has focused on creating more alignment between ECE and K–12 schools. This movement focuses on supporting children's cognitive, social-emotional, and school engagement skills. Scholars such as Rima Shore argue that PreK–3rd is critical in part because high-quality preschool programs alone do not guarantee academic success. Indeed, as the Head Start Impact study showed, early gains are not always sustained into elementary school. Shore suggests that a key to sustaining those gains is carrying forward quality improvements into the early elementary years and creating alignment in organizational structure, goals, and instruction. PreK–3rd scholars Kristie Kauerz and Julia Coffman offer eight essential areas of alignment for PreK–3rd initiatives: cross-sector work, administrator effectiveness, teacher effectiveness, instructional tools, learning environment, data-driven improvement, family engagement, and continuity and pathways.

Chicago Child–Parent Centers

The program most often cited in support of a PreK–3rd approach is Arthur Reynolds's study of the Chicago Child–Parent Centers (CPC). CPC provided education, family, and health services starting with a half-day preschool program for

3- and 4-year-olds followed by half- or full-day kindergarten. After kindergarten, school-age services, including reduced class sizes, the addition of teacher aides, parent-program activities, and coordinated instructional activities, were offered in linked elementary schools until age 9. One evaluation of CPC compared children who continued participating in the first- to third-grade part of the program with those with no participation in the first- to third-grade part of the program to assess the added benefits of the extended childhood intervention into the primary grades. Findings suggested that the extended childhood intervention was related to lower rates of special education and grade retention relative to the less extensive intervention and had the highest performance across outcomes. However, there are two important caveats to this study. First, it should be noted that the extended intervention was not significantly related to educational attainment. Second, it should be noted that eligibility for the extended intervention was not randomly assigned in this evaluation. Instead, researchers compared extended intervention participants with similar children who did not participate in the extended intervention.

PreK–3rd and State Policy

Findings from the CPC study and other studies supporting PreK–3rd have given way to policy changes in many states. One case study that highlights examples of how policy can help create an infrastructure for PreK–3rd is Washington state. In 2005, Washington's governor created a committee to review the state's education system. Three priorities emerged: higher education, K–12, and early learning. This is known as the first time that ECE and K–12 were brought together at a state policy level. Previously, the worlds had operated under different policy, funding, and regulatory systems. This paved the way for several PreK–3rd policy changes in the state, including the creation of a Department of Early Learning, the adoption of voluntary full-day kindergarten, and the development of a 10-year plan to align prekindergarten and K–3 practices.

Conclusion

Over the past two decades, we have seen an unprecedented focus on policies targeting preschool and quality improvement, perhaps because of the large preschool program evaluation literature to draw from that has begun to inform long-standing policy debates. Less attention has been paid to policies for children birth to age 3. Though there are a number of center- and home-based programs serving infants and toddlers, we know much less about what works best for whom during those critical years of development. Still, considering these bodies of evidence together, it is clear that the United States has made significant progress in its investment in ECE as a vehicle for promoting educational success and reducing disparities. As policy makers continue to focus on ECE, perhaps there will be greater investments in policies across the years from birth to age 8 to help ensure that all children are provided with the early educational opportunities that promote healthy development and learning.

POSTMODERNISM

If postmodernity refers to the social, economic, political, and cultural conditions operating in society, then postmodernism concerns the ideas and philosophies that are used to theorize the conditions of postmodernity. The basic premise is that knowledge claims must be located contextually and reflect the conditions of the contemporary world in all its diversity. Accordingly, postmodernists doubt modernist discourses of truth, reason, certainty, universality, and progress, and reject grand historical narratives of liberation and revolution. Postmodernism aims for more just and democratic societies by providing the tools to analyze and reconstruct modernist systems of organization and thought by investigating difference, hierarchies, power relationships, and contradictions in everyday life. This entry explains some

of the concepts related to postmodernism and discusses how theories have been used to analyze contemporary early childhood education (ECE).

Postmodernism: An Explanation

Depending on the discipline area (e.g., science, art, architecture), postmodernism has various meanings and uses different terms. Debates about the differences between modernism and postmodernism are often reliant on how modernism is conceptualized and whether postmodernism is seen as a reaction to the philosophical assumptions and values associated with the modern period of European history called the Enlightenment. However, the difference between modernism and postmodernism is not a simple matter of chronology or reaction. Rather, different sets of social and cultural practices are operating that are characterized by alternative ways of thinking and doing. This is reflected in how epistemological (what counts as knowledge), ontological (how the nature of reality is understood), axiological (the role of values), methodological, and ethical assumptions about the world have changed and continue to do so.

These different ways of thinking and doing are contested and mark a shift rather than a complete break between modernism and postmodernism. A complete break is not possible given that modernist systems remain in existence. Those who have successfully combined aspects of modernism and postmodernism have created new conceptual spaces and generated new forms of thinking, theorizing, and doing. Four interconnected but different ways of thinking and doing are discussed: questioning universalism or metanarratives, rejecting the Western idea of unified reason, relinquishing realism and representational epistemology, and working across traditional disciplinary boundaries.

Postmodernists question and reject general theories (metanarratives) that provide overarching explanations of the natural or social world within specific knowledge domains such as philosophy and social theory. These metanarratives have been applied as universal laws, claimed as *the* “truth” and used to legitimate political activities

and scientific progress. The idea of scientific and technological progress producing better societies has been shattered by the genocide and destruction of World War II and ongoing atrocities since then, as well as the continuing damage to the planet. Postmodernists prefer little narratives because unlike metanarratives, they are not used as overarching methods of validation, legitimization, and control and because they offer spaces to investigate everyday conditions in the context of society. The focus of social and cultural analysis then is minor knowledges and discourses and the societal conditions in which they operate. Analysis might consider identity, difference, and diversity (e.g., ethnicity, race, class, gender, religion, sexuality).

Rejecting the Western idea of unified reason involves discarding the humanist (modernist) notion of the individual rational subject with a fixed identity that endures over time, and which strives for the achievement of reason in social and political practice. Postmodernists argue for a subject that is decentered, contradictory, and multiple. They maintain there is no core or essential identity (of child, teacher) because identities are in continual processes of change, dissolution, and reconstruction. This means that there is no essentialized way of knowing, being, and “doing” ethnicity, woman, father and that contradictory positions can be adopted depending on the circumstances. Rejecting essentialism and rational thinking is about resisting universal approaches, causality, order, and prediction in favor of multiplicity, uncertainty, and complexity.

Relinquishing realism and representational epistemology is generally known as the crisis of representation. Modernism holds to the idea of an objective natural reality, where reality is independent of human minds, societies, social practices, and methods of investigating and representing reality. Thus modernists contend that what exists can be represented objectively (truthfully) by ideas and works of art. Postmodernists see such representations as constructs produced by science (art, philosophy) and language, rather than objective representations of *the* “truth.” They opt for

multiple truths/ways of seeing because such representations are socially constructed at different times, in different places, and by different people. Rejecting naive realism and representational epistemology (objectivity and one truth) necessitates perspectives that are partial, interpretative, relative, and anti-foundational.

Traditional disciplinary boundaries are being dismantled both within and across disciplines. Differences have been deconstructed to expose links between philosophy and literature, history and philosophy, and the sciences. The aim is, as Steven Best and Douglas Kellner suggest, to remove “fact-value and theory-practice” binaries (p. 258) and for ECE, dichotomies of teaching–learning, work–play, and adult–child. In Western modes of thought, removing distinctions between disciplines and challenging dominant ideas has facilitated different ways of thinking and doing. For instance, identity politics enables perspectives of nondominant groups to be recognized as valid. Postmodern approaches are more democratic, inclusive, and equitable. They can investigate how aspects of identity intersect (e.g., how ethnicity, socioeconomic status, gender, and sexuality work together in constituting identities), and in so doing disregard traditional discipline boundaries to reconstruct complexities involved in everyday lives.

Postmodernism, Postmodernity, and Early Childhood Education

Postmodern theories are political because they have identified modernist discourses that control, classify, and “normalize” children, childhood, families, and early childhood education, and exposed them as regulatory, inequitable, discriminatory, and limiting. These discourses include the all-encompassing metanarratives of child development and standards, and their respective incumbents.

Questioning universalism or metanarratives has been important in challenging the field’s reliance on child development knowledge. Developmental psychology remains the major informant of ECE and is such a taken-for-granted aspect of everyday life that it is almost imperceptible. Challenges to

this dominant modernist discourse are based on the grounds that aspects of child development such as developmentally appropriate practice, child centeredness, and constructivism have been portrayed as applicable to all children everywhere at all times. Similarly, Jean Piaget's stages of development, and aspects of behaviorism and social and cognitive development, have been applied globally as if culture and context are irrelevant and as if there are no alternative ways of understanding young children. The pervasiveness of metanarratives has resurfaced again recently, with Western-based ECE standards adapted for a range of countries in Africa, and scales to measure children's development produced for several countries in East Asia and the Pacific. These strategies seem to be about normalizing and standardizing thinking and doing, rather than realizing claims that standards will make ECE more equitable.

Another powerful but tacit assumption is that child development knowledge is a legitimate basis for curriculum decision making. Educational goals have political and moral origins, but much foundational child development knowledge has biological origins. Child development theories can offer guidance about suitable times to present information to young children, but they are unable to inform educators about what to teach, why, and how. Despite calls to the contrary, this overwhelming focus on child development (as curriculum) has resulted in very little research about the politics of children's learning and the politics of teaching. Contestation about ECE curricula continues, with debates about the place of discipline content in the before-school sector in countries required to implement national curriculum frameworks.

Postmodern theories such as feminist poststructuralism have enabled research about gender and power relations in ECE in terms of how the profession is feminized, men in ECE, and the ways in which gender is a fundamental and inequitable aspect of children's everyday lives, including contexts of learning and teaching. Queer theory has also been drawn on to investigate matters related to men in ECE, as well as children's sex play and sexual identities. Research about ethnicity, race,

class, sexuality, and linguistic diversity of children, families, and teachers has used postcolonial, poststructural, queer, feminist, and feminist poststructural theories. Combinations of theories have also been used to examine intersections among these factors, and studies that incorporate intersectionality are becoming more common. These theories bring issues of power, "othering," and gender to the fore. Research outcomes include equity strategies for classrooms that address marginalization and discrimination based on race, ethnicity, gender, sexuality, and lack of proficiency with the dominant language.

Popular culture has been an enduring theme in ECE research in relation to consumption, media generally, information and communications technologies, and superhero play. Gender has featured in researching popular culture, particularly with regard to superhero play; and feminist, feminist poststructural, and deconstructive approaches have been adopted for this purpose. Commonalities among these investigations include recognition of the multiple identities that children adopt, the significance of power relations in children's everyday lives, the strength of child agency, and the existence of alternatives to stereotypical metanarratives. They also confirm ECE settings as spaces for children to learn about ethical and political practices.

The postmodern approaches discussed earlier focus on discourse and discursive/linguistic practices. Recent postmodern research has adopted posthumanism, where material and affective aspects of children's lives are explored by probing mutual engagement among humans, nonhumans, and matter. Privileging these relationships attends to dimensions previously ignored in Western research, but such relationships are part of the everyday lives of many Indigenous peoples. They have applicability to environmental research, create spaces for decolonization, and open possibilities for engaging children in ways unknown in Western ECE curricula.

Postmodern approaches have also made room for the idea that children have social agency, something that was not recognized in the developmental metanarratives of Piaget, Erik Erikson, and others.

Children and childhood can now be conceptualized as cultural and historical constructions rather than biological commodities on whom research is done. Postmodern theoretical perspectives and new methodological approaches make it possible to move beyond positioning children as research objects in contexts devoid of power relations and which lack any cognizance of inequities. Such research has also moved past imposing adult meanings and revealing what was already in existence.

Methodologies now focus on researching with children rather than on them; listening and hearing children; involving them in research design, data gathering, analysis, and reporting; and adopting data collection approaches that engage children meaningfully. They involve postmodern understandings of knowledge, the nature of reality, ethics, values, and researcher reflexivity. They provide perspectives that are partial and contingent, and which traverse traditional disciplinary boundaries. This is a long way from the child of developmental psychology, seen as a research object and a progressively developing entity without agency to be correctly socialized through surveillance and regulation into a socially acceptable “normal” adult.

The Impact of Postmodernism on Early Childhood Education

Early childhood education is a site of competing discourses where dominant understandings of child development, policy, children, families, learning, and teaching are contested. While dominant discourses retain their power and legitimacy, postmodernism has provided alternative ways of thinking and doing, enabling the identification of groups and practices that have been marginalized and disempowered, as well as making visible some of the politics of how and why this has occurred. Postmodernism offers a wide range of epistemological, ontological, axiological, ethical, and methodological strategies to inform the goal of achieving more socially just and equitable approaches to ECE. While they do not hold all the answers, these tools provide insight into issues that stretch beyond the scope of modernist

approaches and establish ECE settings as important places of identity construction.

POVERTY EFFECTS

Poverty reflects not only lack of material assets, but also a lack of social capital—a sense of belonging, cultural identity, respect, dignity, and access to information and education. Of approximately 2.2 billion children in the world, one billion live in poverty. Poverty among children is not confined to children in the developing world; some economically advanced countries also have high numbers of poor children. Among economically advanced countries, the United States has the second highest percentage of children (22% of all children and 25% of children under 6 are poor; Romania has the highest percentage). Regardless of geography, the effects of poverty generally remain the same: higher mortality rates and detrimental child outcomes. Yet children do not necessarily experience the effects of poverty in the same ways or to the same degree; the effects depend on exposure to risks, individual variation, and exposure to protective factors. This entry examines some of the factors that determine whether poverty will impact a child and if so, to what extent.

In addition, this entry examines the many short- and long-term effects that poverty can have on a child, including but not limited to physical, emotional, and cognitive impacts.

Factors Influencing the Effects of Poverty

The effects of poverty are difficult to determine and occur at both neural and behavioral levels. Moreover, the breadth, depth, and longevity of the effects are not the same for all children. However, it is clear that poverty is harmful to children, affecting both immediate and future functioning negatively across all domains of development and measures of achievement. There are a number of factors in a child's constellation of poverty.

Cumulative Risks

The more risk factors to which a child is exposed, the more the child's development is compromised. Although intensity of risks also matters, aggregate number of risks matters more. For example, being a child soldier even briefly is a high-intensity risk factor, but the number of war trauma incidents experienced predicts mental health problems more closely than categorical exposure. Likewise, a child who loses a parent *and* is exposed to household violence has a higher likelihood of developing post-traumatic stress disorder than does a child who experiences violence but has not lost a parent. Effects of cumulative risk endure over time: A child who experiences early nutritional deprivation is less able to benefit from a high-quality adoptive home later than is a child who never experiences early deprivation or experiences it only briefly. Exposure to cumulative risks also may sensitize a child to later risks; for example, early exposure to hunger renders a child more sensitive to and less able to overcome challenges resulting from later exposure to hunger.

Depth, Duration, and Timing

Depth of poverty—how far below the normal standard of living a family is—reveals how tolerable

or abysmal a child's experience in poverty is. In 2010, the World Bank reported that 400 million children lived in extreme poverty (\$1.25 a day or less); 10% of American children live under half the poverty line, which means they live on less than 50% of what the Census Bureau annually determines to be the federal poverty threshold, commonly called the poverty line. In 2013, the U.S. poverty line was set at \$16,057 for a family with two parents and one child; a child living under half the poverty line lived in a family making approximately \$8,000 or less. The deeper a family's experience of poverty—the poorer it is—the greater the effects of poverty. Duration relates to the longevity of poverty; many families cycle in and out of poverty over many years as they hover around the poverty line. If poverty is chronic, the effects on child outcomes are greater. Timing is also important; the younger children are when they experience poverty, the bigger the effects of poverty because of both environmental effects on brain development and the fact that family life dominates young children's lives. Early experiences with poverty are more difficult to overcome than later experiences.

Dimensions of Poverty

Lack of adequate finances is the most obvious measure of poverty. The average poverty line in developing countries is \$2 per day. In the United States, the Census Bureau determines the poverty line on the basis of annual income and family size; in 2013, that line was set at \$23,624 for a family of four people. Experts who study poverty note that expenses vary greatly by location, so living above that line does not represent economic security. Research indicates that a family needs an income of about twice the poverty line to meet basic needs. For example, a family living in Washington, D.C., needed \$89,600 to be economically secure, while a family living in Tunica County, Mississippi, needed \$50,725. Adequate finances allow families to afford three meals a day with some meat, fresh fruit, and vegetables, two pairs of shoes that fit, an Internet connection, books, games, and other resources.

However, income represents only one dimension of poverty. Other dimensions include access to subsidized social services and inclusion in the social fabric of the community. Consider an asylum-seeking family that receives a monthly stipend to pay for shelter and food but is utterly isolated. The family members may have no access to employment opportunities, health, education, or legal services; they cannot work, go to school, or get medical help. They may be unable to speak the language of the host country, causing further isolation. They also are likely to be without an extended family or other social network that can provide the basic social community families need for well-being. The family may play no role in religious, neighborhood, or civic groups, and may have no friends with whom to socialize. Social dimensions of poverty affect people with disabilities or mental health problems, members of specific ethnic groups, widows, orphans and foster children, homosexual and transgender individuals, immigrants, and other marginalized people who have no social capital.

Individual Differences

Even after accounting for the factors above, one sees marked differences in child outcomes that are not explained by exposure alone but result from individual differences in children. Some children are more resilient than others. There are complex interactions between biological and behavioral characteristics; genes and temperament impact outcomes. Children's inborn sensitivity to environmental context and their constitutional capacities make a difference in how they respond to the stressors they experience in poverty. Children born with higher levels of intelligence and a greater capacity for emotional self-regulation, for instance, fare better in the face of poverty than other children—though poverty will still take its toll.

Interplay With Protective Factors

Resilience also depends on how many positive, protective factors exist to counterbalance the risks associated with poverty. Children exposed to multiple risks are less likely to experience persistent

adverse effects if they also encounter multiple protective influences. Known protective influences include sufficient nutrition (e.g., micronutrients, folate, being breastfed, iron supplements); higher parental education or language stimulation in the home; programs promoting responsive parenting; preschool participation, especially in high-quality programs; social support available to parents; and, for institutionalized children, early adoption. The most important predictor of child outcomes appears to be the extent to which threats can be reduced by a supportive adult who helps a child cope with adversity and restores the child's sense of well-being, both physically and emotionally.

Effects of Poverty on Child Well-Being

The depth and longevity of negative outcomes of poverty depend on a child's unique experience of poverty; outcomes are associated with the constellation of risk factors the child experiences as related to low levels of material assets, social assets, or both. The causes and consequences of poverty during early childhood are usually inseparable and interact in vicious cycles. For example, homelessness, hunger, inadequate parenting, limited access to and low quality of care and education, mental and physical illness, lack of decent medical care, social isolation, and so forth are simultaneously risk factors and outcomes of poverty. Together, these factors in the poverty constellation threaten children's chances of survival and well-being in all developmental domains.

Child Mortality Rates

Poverty greatly reduces children's chances of survival. In 2012, 6.6 million children around the world died before their fifth birthday. The reasons for early death are mainly related to maternal and child health problems. In part because of a poor diet, many poor women give birth preterm. Many women living in poverty in developing countries do not have a skilled birth attendant with them to help deal with asphyxiation, infections, and other birth complications. Pneumonia, diarrhea, malaria, and malnutrition are major causes of death for

children under age 5. Globally, more than 40% of under-age-5 deaths occur in the first month of life, often due to preterm and low birth weight complications.

Effects on Children's Developmental Domains

Poverty jeopardizes all areas of children's development including those discussed in the following sections.

Physical Growth and Health

Children's physical growth and health is at risk in poverty because of challenges to nutritional intake, exposure to illness and disease, and the incidence of violence. The foundation of healthy growth is built on sufficient and nutritious food intake, commonly unavailable to poor families. Although breastfeeding provides optimal nutrition and protective antibodies and is free, infants in poor families are less likely to be breastfed than other infants. In the United States in 2011, 71% of infants in poor families ever breastfed versus 91% of infants in affluent families; at age 6 months, the breastfeeding gap was even larger (38% vs. 68% respectively). In developing countries, approximately 38% of infants exclusively breastfeed. Breastfed children have at least a sixfold chance of survival compared with their nonbreastfed peers. Low breastfeeding rates can be due to the mother's difficulty in spending extended time with her infant when she has to work or lacks information on breastfeeding. Poor families often also lack access to healthy foods that provide adequate levels of protein, vitamins, and nutrients, such as fruit, vegetables, meat, and fish. Poor children are often deficient in iodine, iron, and zinc. In many cases, poor families may have access to inexpensive, highly caloric foods, such as fried chips, that lack nutrients and contribute to obesity, which can co-occur with malnutrition. Approximately 14% of American households were food insecure in 2014, meaning that more than 15 million children were hungry, and 25% of children under 5 (161 million children) worldwide were found stunted in 2013, meaning that chronic malnutrition had caused abnormally low weight, height, and cognitive development.

Being poor is associated with high rates of child illness and disease as well—especially when mothers die, still a significant problem in the developing world. Preventable illnesses are common: Child immunization programs are not yet universal, although great gains have been made in the last decade; malaria affects perhaps as many as 600 million children in 90 countries; HIV remains problematic, and diarrhea is common. Poverty is also linked to unsanitary and unsafe environments in many cases, with families or solitary children living on the streets, in abandoned buildings, at garbage dumps, or in cars or overcrowded rooms. It can mean living in places with exposure to high levels of lead, manganese, and pesticides, and to arsenic, frequently found in well water. Using groundwater for both bathing and cooking, or drinking untreated water, also raises incidences of illness.

Maltreatment as a Threat to Children's Health

Children in poverty are exposed at higher rates than other children to violence, both within their households and in their communities. Rates of physical and sexual abuse and child neglect are difficult to calculate, but the effects are multiple and include child aggression, trauma, brain impairment, physical injury, sexually transmitted diseases, disability, impaired cognition, depression, decreased productivity, and death. Hunger, environmental toxins, illness, and violence can impair not only physical well-being but also other areas of development, contributing to atypical brain development, particularly in the first 3 years of life; learning problems; failure to meet major developmental milestones; impaired motor skills; decreased activity and motivation levels; and psychosocial problems.

Social and Emotional Development

Poverty is typically a source of stigma, isolation, embarrassment, and shame. Children may try to hide the fact that they participate in a free lunch program or stay in a motel or park instead of a home. Societal pressures to conform to middle-class

lifestyles—owning at least two pairs of shoes, having access to healthy meals on a regular basis, clean water for bathing and washing—are impossible to meet for many poor families. The result is not only individual shame, but communal disregard. In almost all countries, poor people, children in particular, are the least likely to have a voice in local events or a presence at community gatherings. They are often marginalized, ignored, left out, or viewed with disdain or disgust.

Children in poverty experience higher than average rates of both internalizing and externalizing behaviors. Internalizing problems common among poor children include a sense of feeling stigmatized, isolated, left out, overlooked, or invisible; embarrassment or shame; anxiety; depression; poor self-esteem; and a sense of vulnerability and dependence. Children in poverty who are hungry, lacking adequate sleep or shelter, or living with excessive stress or insufficient nurturing also show high rates of externalizing behaviors: oppositional behaviors, such as aggression, fighting, defiance, or trouble obeying authority; blaming others for problems; not abiding by rules (e.g., stealing); difficulty getting along with peers; impulsiveness; low self-regulation; attention-deficit/hyperactivity disorder; and conduct disorder. It has been shown that chronic poverty is strongly associated with feelings of anxiety, unhappiness, and dependence, whereas current poverty is strongly associated with acting out, disobedience, and aggression.

Cognition and Academic Achievement

Research shows that the effects of poverty are especially large for cognitive outcomes, even more so than for social and emotional outcomes. Negative outcomes are exacerbated when children experience poverty during early childhood when brain development occurs rapidly and is highly influenced by the environment. The cognitive implications of poverty begin in infancy, and gaps in executive functioning and achievement between poor and other children widen as children age.

When pregnant women fail to get adequate nutrition, their infants tend to be born too early

and with small head size and brain weight. These infants are at risk for learning disabilities, especially if they fail to experience good nutrition and early intervention in the first few years of life. Children who chronically lack adequate nutrition—having too little protein, energy, and nutrients during the earliest years when brains are developing rapidly—are at risk for brain impairment, failure to thrive, and failure to meet foundational developmental milestones. These problems affect 5% to 10% of American children under age 3, and up to half of children in developing countries. Young children who are undernourished are slower than others to develop motor skills, show typical activity levels, and lack the energy and motivation to explore their environment. In turn, they have slower cognitive development and elicit less stimulation and attention from their parents and other caregivers, which further diminishes cognitive development. In 2012, whereas 75% of moderate- and high-income children in the United States were gauged ready for school at age 5, only 48% of low-income children were gauged ready, based on early math and reading skills, learning-related problems, problem behaviors, and physical health.

Children in poverty are less likely to enroll in and stay in school. The highest dropout rates in many developing countries occur in first and second grades. In the United States, although high school graduation rates reached an all-time high in 2014 at 80%, there was a gap of 16 percentage points between low-income students and everyone else. Low-income children are more likely than others to require special education services and remedial services in school, repeat a grade, or be suspended from school, and less likely to graduate on time, attend college, or have the necessary knowledge and skills for higher paying jobs.

Incidence of Disabilities and Developmental Delays

Causes of disabilities and developmental delays are numerous and complicated, and largely influenced by genetics. Yet there are significant environmental influences as well, to which families in

poverty are exposed at high rates. Prenatal influences include insufficient diet, viral infections, toxemia, and exposure to alcohol or drugs. Perinatal influences include premature birth, low birth weight, and unassisted delivery resulting in head injury or lack of oxygen for the newborn, which can contribute to mental retardation, seizures, cerebral palsy, and deafness. Postnatal influences include lack of adequate medical care and early interventions, incomplete immunizations, exposure to toxic environments (e.g., high lead levels, arsenic, pesticides), maternal depression and lack of maternal responsiveness, and nutritional deprivation. None of these factors alone necessarily causes a disability or delay, but they are thought to contribute to the higher incidences of some types of disabilities among children living in poverty because of their relatively higher exposure.

Effects on Access to Services

The poor are most in need of basic services and the least likely to receive them, especially high-quality services. First, 1 in 3 children worldwide does not have a birth certificate, and those who do not are almost always from poor and marginalized families. Besides simple acknowledgment of a child's existence, registration can have practical effects on accessing health care and immunizations, school enrollment, enforcement of child labor laws, ensuring a child's right to nationality, protection against abuse and trafficking, and, later in life, opening a bank account, voting, obtaining credit, or gaining employment. Second, although equitable access to comprehensive, affordable basic health care is endorsed as a basic human right by almost every country, poor children and families frequently lack access to health services. Pregnancy checkups, immunizations, and subsidized medical and dental care are often insufficiently available. Third, poor children do not have access to care and education programs at the same rates as other children. Around half of all children around the world do not have the opportunity to participate in any preprimary education and, in 2015, 57 million primary-school-age children were not enrolled in school.

Children in poor families were four times as likely not to be in school as children in rich families. Barriers include costs (especially for preprimary programs); homelessness or frequent moves, which disrupt enrollment; language and legal barriers for immigrants, asylum seekers, and refugees; and child labor, which keeps children from attending school regularly. Being a girl also remains a barrier in many countries. Missing school is only part of the problem, however; when poor children do attend school, they tend to receive the lowest quality care and education.

Long-Term Effects on Individuals and Societies

Children growing up in poverty are less likely to survive until adulthood than other children and more likely to have a lifetime of greater susceptibility to physical and mental health problems. They are more likely to have cardiovascular disease, hypertension, obesity, diabetes, and strokes. They are more likely to suffer from depression, anxiety disorders, and substance abuse. They are more likely than others to smoke, engage in early sexual activity, drop out of school, be arrested, be a victim of a crime, have a low-paying job, not own a home or a savings account, and not have access to credit. They are also more likely than others to be in unstable or conflict-ridden relationships, have less social support than they need, and show less productivity for their families and society.

It is impossible to capture the human and moral costs of poverty in a monetary sense, but economists do estimate costs to national markets based on lost productivity and required social services. In 2013, Richard J. Coley and Bruce Baker estimated that child poverty cost the U.S. economy an estimated \$500 billion per year or 4% of the GDP.

Protective Factors That Ameliorate Effects of Poverty

Insufficient income alone does not dictate that an individual child will manifest the problems described earlier. Outcomes depend on the context

in which children experience poverty. Young children living in a warm, functional, extended family environment may fare very well; children living in a chaotic, unpredictable environment with unstable or unhealthy primary relationships are likely to fare less well. Parenting plays a critical role, as does public policy.

Parents' Well-Being and Parenting Practices

Caregivers' own well-being and parenting skills have a tremendous impact on child outcomes. This is true regardless of income, but parents living in poverty tend to experience high levels of stress, experience less well-being, have low educational attainment, and demonstrate lower quality parenting skills than parents not living in poverty. When parents (a) use warm, responsive interactions; (b) are stable and consistent; and (c) are not hostile and provide positive, nonviolent discipline, children fare better than with parents who are harsher and inconsistent. In addition, the amount of time parents spend talking to, reading to, engaging with, and otherwise stimulating their children has important effects on cognitive and language development, among other domains. Primary caregivers play a paramount role in protecting children from the consequences of poverty if they can maintain children's physiological and psychological well-being in the face of stressors. Good parenting is more likely to occur when strong social and instrumental supports exist for low-income parents.

Public Policies That Reduce Negative Effects of Poverty

Government policies that aim for high rates of employment—ensuring families have an income—and provide a large number of services reduce the effects of poverty on disadvantaged families. What matters is not a country's absolute level of income but how the money is spent. For example, the Czech Republic and Portugal have equivalent per capita incomes (\$25,000), but Portugal's child deprivation rate of 9% is three times lower than that of the Czech Republic (27%). (The United

States has a per capita income of \$54,000 and a child poverty rate of 22%.) In *Measuring Child Poverty*, a multinational 2012 report card on child poverty, the United Nations Children's Fund (UNICEF) states, "The level of risk incurred is not a function of chance or necessity but of policy and priority" (p. 26). Several approaches working in tandem can reduce the effects of child poverty:

Increasing Family Income. Job creation policies and family income supplements are effective in reducing poverty and its consequences. These include programs that supplement parents' income directly, such as by conditional cash transfer programs, food aid programs, disbursing special revenues (e.g., casino revenues) to vulnerable families, and reimbursements through tax credits. Programs that improve financial literacy, such as microloan and budget-management programs, also improve child well-being by increasing family income.

Decreasing Exposure to Risks. Programs that work to reduce or eliminate risk factors associated with poverty also reduce the effects of poverty. Examples include immunization programs, nutrition programs, and creating and maintaining healthy living environments, such as affordable housing, lead-free environments, reductions in pollution and second-hand smoke, gun control laws, and hygiene and sanitation campaigns. Investments in infrastructure—building health clinics, renovating schools—also have been shown to improve health and well-being in impoverished communities.

Increasing Protective Factors. Because protective factors can ameliorate the risks associated with poverty, investments in child and family programs are socially and economically sound. These include, but are not limited to, comprehensive, affordable medical care; breastfeeding campaigns; food aid programs; paid parental leave policies that promote breastfeeding and bonding; parenting support and education programs; early intervention; universal access to high-quality infant/toddler programs and preschool; fair funding policies that improve public school quality in poor neighborhoods; and adoption for institutionalized children.

In sum, the effects of poverty are pernicious and lifelong in many cases, affecting children's health, social-emotional well-being, and achievement, especially if they are exposed to multiple risk factors; experience deep, chronic, or early-in-life poverty; are biologically and temperamentally vulnerable; and experience too few protective factors. Although policies and programs can offer protective buffers that mitigate the negative consequences of poverty, they require human and financial investments. Economists James Heckman and Dimitriy Masterov stated that such investments are rare in that they have "no equity-efficiency tradeoff" (p. 1), meaning there is no downside to these investments.

PREJUDICE

See Development of Prejudice

PREKINDERGARTEN

In general terms, prekindergarten (pre-K) is a publicly funded classroom-based early childhood education program that children, typically 4 years and sometimes 3 years old, attend prior to kindergarten entry. The purpose and intent behind pre-K is to provide children with academic and social learning experiences that prepare them for success in elementary school. In the United States, there are three types of pre-K programs: the federal government's Head Start program, state-based pre-K programs, and city/community-based pre-K programs. While these programs serve more than 2 million children and their families, there are numerous political, financial, curricular, programmatic, instructional, and familial issues affecting them. This entry begins by examining the emergence of pre-K. It then explains the differences between Head Start, state-based pre-K, and city/community-based pre-K programs and provides a brief summary of what each program is designed to do. Lastly, it highlights past, current, and future challenges for these programs.

The Emergence of Pre-K

In the United States, policy makers' interest in pre-K programs, specifically Head Start, emerged

in the 1960s as a part of President Lyndon Johnson's War on Poverty. At that time, researchers and policy makers framed this program as a vehicle that could break what they termed the cycle of poverty. These stakeholder groups identified the root cause of academic failure, which leads to economic failure, being children's home environments. The goal was for this comprehensive early education program to break this cycle of poverty by giving low-income children a head start for elementary school by teaching them the skills and knowledge needed to succeed in kindergarten.

State-based pre-K programs emerged after it became apparent the federal government's Head Start programs were unable to serve all eligible children. The evolution and expansion of these state-based programs was slow. As reported in *The State of Preschool 2014: State Preschool Yearbook*, only 10 states offered pre-K by 1980, 28 states by 1991, and still now, only 40 of the 50 states offer some form of pre-K program. Like Head Start, most of these state-based programs are intervention programs serving particular populations of children. Lastly, many cities and communities across the United States currently grant access or are in the process of offering access to pre-K to all 4-year-olds who live within their communities.

Federal Government and Head Start

Project Head Start emerged from the Economic Opportunity Act and the Elementary and Secondary Education Act (ESEA) as part of the Johnson Administration's War on Poverty in 1965. What began as an 8-week summer program designed to prepare low-income children for kindergarten entry is now a dual-generation program serving more than 800,000 children between the ages of 3 and 5 years and their families across the United States. The Office of Head Start operates out of the Department of Health and Human Services (HHS). The HHS directly funds more than 1,600 local grantees (organizations, local government agencies, or school districts) to provide Head Start programs that promote children's school readiness by enhancing their social and

cognitive development. On average, the federal government spends more than \$7,500 per child and provides children and their families with educational, health, nutritional, social, and other services designed to meet their local needs as well as the Head Start Program Performance Standards. These standards detail such requirements as what type of learning environment each program is to offer, including physical space, curricula, assessment and transition requirements, the type of communication and partnerships programs are to establish with families, and criteria for hiring teachers and staff.

State-Based Pre-K Programs

Similar to Head Start, the vast majority of state-based systems of pre-K are intervention programs for children who policy makers deemed “at risk” for school failure—be it poverty, involved in foster care, homeless, or English language learners, for example. Because the intent behind these child-focused programs is almost exclusively on ensuring all children enter elementary school ready to succeed, all state-based programs have early learning standards that children are to attain by the end of pre-K. Many states also have academic achievement measures children must take to measure whether they have acquired the knowledge and skills outlined in the early learning standards. Across the states, issues of teacher certification, where and who offers pre-K (e.g., the public schools and/or community-based programs), and how long programs last (half day vs. full day) varies significantly.

In terms of participation in these state-based pre-K programs, as reported in *The State of Preschool 2014: State Preschool Yearbook*, as of 2014, close to 30% (more than 1 million) of the nation’s 4-year-olds and close to 5% (200,000) of 3-year-olds participated in a state-based pre-K program. State governments spend significantly less on pre-K programs (\$4,100 per child) than traditional kindergarten through Grade 12 (K–12) programs (\$12,400 per child) or the federal government’s Head Start program. Because of this, the quality of services being offered to children is

an important issue surrounding the establishment and funding of these programs. For instance, the National Institute of Early Education Research (NIEER) rates each state-based pre-K program using 10 criteria: comprehensive early learning standards, teacher degree requirement, specialized training in pre-K for teachers, assistant teachers having a CDA or equivalent, teachers taking at least 15 hours of in-service training a year, a class size lower than 20 students to 1 teacher, a staff-to-child ratio of 1 to 10, health/support screenings, meals provided to children, and state monitoring of programs. In 2014, only five states met all 10 criteria, and over 40% of the nation’s children attended pre-K programs that met less than half of these benchmarks.

City/Community-Based Pre-K Programs

Since most states do not offer or fund universal pre-K programs, many cities and communities offer (e.g., New York City and San Antonio, Texas) or are in the process of working toward (e.g., Chicago and Los Angeles) universal pre-K programs that allow all 4-year-olds who live in that city the opportunity to attend these programs free of charge. These universal programs often draw from local, state, and federal funds to offer all children access to either a half-day or full-day pre-K program. Similar to the state-based pre-K programs, the intent behind these child-focused pre-K programs is almost exclusively on ensuring that each child is academically and socially prepared to succeed in elementary school.

Past, Present, and Future Issues

Political and Fiscal Issues

This establishment of government-funded pre-K continues to be politically controversial. While Head Start, state-based, and city/community-based pre-K programs continue to grow in size and reach, their livelihood is dependent upon the financial support of policy makers. An example of the political tensions that exist over publicly funded pre-K can be found in the Nixon administration’s responses to Johnson’s *Great Society* education policies. For

instance, Nixon created the National Institute of Education (NIE) to investigate the return that society received for its investment in education. The work of NIE and studies such as the Westinghouse Learning House's evaluation of Head Start in 1969, which suggested that the IQs of students in the program quickly faded, raised enough concerns over the effectiveness of these government-funded programs that it gave Nixon the political cover needed to veto the Comprehensive Child Development Act of 1971. The Act was to expand the federal government's funding of child care and education while creating a framework for child services.

Researchers responded to these critiques of whether Head Start improved children's learning by arguing that while increases in IQ might not be sustainable, students who participated in such programs were more successful academically and socially as they continued through school than those students who did not receive these services. These longitudinal studies, which examined a range of early childhood programs outside of Head Start, spawned the investment argument. This argument has slightly shifted the premise for funding pre-K. Rather than breaking the cycle of poverty for others, the original intent behind Head Start, emphasis is now on funding pre-K to save taxpayers money.

By positioning pre-K through its ability to save taxpayers money, it can limit policy makers' focus to providing pre-K only to those children who offer the best return on their and taxpayers' financial investment. In addition to taking a targeted rather than universal approach to pre-K, the investment argument makes these programs dependent upon their ability to improve student achievement at a reasonable cost; failure to do so may lead to the termination of programs or reduced political and/or fiscal support. Lastly, because pre-K is typically framed as a targeted intervention program, its funding is often cut when the federal, state, and/or local governments face budget shortfalls.

Lastly, as federal, state, and local governments expand access for children to pre-K programs, these policies can negatively impact private and

nonprofit early childhood centers by taking away significant portions of their clientele.

Issues of Standardization, Academic Achievement, and Accountability

Investing in pre-K programs to improve young children's academic achievement in K–12 education systems, which includes closing the achievement gap, led to the standardization of these programs, meaning that all children who attend pre-K are to obtain and demonstrate that they have learned a specific set of knowledge and skills by the time they leave these programs. This focus on early learning standards and children's academic achievement appears to replace what is known about how children develop and learn with what they are to know and do.

Many within early childhood education worry that these policies and sanctioned practices redefine the purpose of pre-K. Other concerns about the standardization of pre-K include the diminishing role of play-based learning in the classroom and the negative effect of teacher-directed learning activities on children's enthusiasm and curiosity as well as the teachers themselves who are required to make improper use of standardized assessments to measure children's academic achievement. In sum, mandating specific academic and social outcomes for children enrolled in pre-K narrows the broad developmental focus of early childhood education and reframes children's development and learning as uniform and standardized rather than uneven and personalized.

Program and Teacher Quality

Another set of challenges that pre-K programs at the federal, state, and local level face relate to ensuring that pre-K programs and teachers working in them are of high quality. Empirical research shows that quality of programs and well-prepared teachers improve the learning and development outcomes of pre-K.

In terms of program quality, many states are implementing quality rating and improvement

systems (QRISs) for pre-K and other early childhood education services. QRISs are standardized, statewide rating systems designed to assess, rank, and improve the quality of early childhood education and care programs using structural, programmatic, and instructional standards and student achievement outcomes.

Teacher quality encompasses the preparation of teachers as well as the types of interactions they have with children in their pre-K programs. Many states either require or are working toward requiring all pre-K teachers to be state certified. Head Start is also working toward this goal. A primary issue with certification is cost. If teachers are not compensated at the same level as their elementary and secondary peers, they may leave pre-K for other employment opportunities. Lastly, research demonstrates the type and intensity of interactions teachers have with pre-K students can positively affect their learning and development. Because of this, many states require increased teacher training and assess teachers on a regular basis to measure the quality of their interactions with students.

The Role of Families

Since the implementation of Head Start, the role of families and government in educating pre-kindergarteners has become a contentious issue. In general, there continues to be debate across the United States about whether the government, at any level, should play a role in the development and education of young children. Additionally, framing pre-K as an investment that saves taxpayers money by educating specific populations of children appears to blame families for such things as being poor. The investment argument also deemphasizes the role of families in the early education process, and instead, it contends that experts in ECE can design and implement programs that provide children with specific learning experiences that will prepare them for success in public schooling and later life. Lastly, the issue of offering families targeted and/or universal access to pre-K continues to play a role in the debates

around governmental support for families in general, maternal employment specifically, and other issues such as paid family leave.

Conclusion

Pre-K in the United States is an early education program designed to prepare children for success in elementary school. Because access to these programs is not seen as a right for children or their families, pre-K will continue to face a range of political, financial, curricular, programmatic, instructional, and familial issues. Nevertheless, the persistence of the achievement gap, the stagnation in students' level of academic achievement in the nation's public schools, and the economic realities faced by families who need for all adults to be employed outside the home will continue to make it an attractive policy solution to policy makers at all levels of government.

PREKINDERGARTEN PROGRAM EVALUATION

Prekindergarten programs, which require a large investment by state, local, and federal agencies, have been growing rapidly in recent decades. This growth has precipitated a great deal of interest in program effectiveness, and much research has been conducted to determine what types of benefits prekindergarten programs bring and how long those benefits can be expected to last. Comprehensive evaluations of prekindergarten programs take into account the costs of the program, the quality of services that the program delivers, and the characteristics of different programs. This entry describes evaluations of prekindergarten programs, including the types of information they provide and common research designs.

Types of Information Provided by Evaluations

One of the primary goals of prekindergarten programs is to prepare students for kindergarten. Impetus for the increase in public prekindergarten programs was provided in part by evidence that many children entering kindergarten were not adequately prepared. Therefore, one of the most important types of information provided by prekindergarten evaluation programs is outcome data on children immediately after the program or at entry into kindergarten. This information would ideally include data on different areas of children's skills such as social skills, early literacy, and math skills. Child outcome data are most helpful when they can be compared with outcome data prior to the children's entry into the prekindergarten program to provide baseline information on the skills of children entering the program and information about the trajectory of growth for those children during or immediately after completing prekindergarten.

In addition to short-term outcomes, there is much interest in the long-term outcomes for children who participate in prekindergarten programs.

If children are able to benefit from these programs only during and immediately after the programs, the investment in such programs might not be justified. Therefore, evaluations of prekindergarten programs are not limited to the prekindergarten year or to the beginning of kindergarten. Evaluations can examine children's outcomes through their school years and even into adulthood, using measures such as grade repetition, special education placement, degree completion, marriage rates, and mental and physical health factors, in addition to test scores. Outcome scores can be compared with national norms or scores from control groups, as discussed below.

Comprehensive evaluations of prekindergarten programs are not limited to participant outcomes, in either the short or the long term. Evaluations can also provide important information to program providers about the adherence to program standards, quality of the services provided to the participants including interactions between teachers and children, and the characteristics of the participating sites, classrooms, teachers, and children. These factors can be important for program monitoring purposes and can also provide information on weakness or strengths of a particular program that could then potentially be addressed by the program providers individually or be addressed through policy changes.

Evaluation Designs Using Control Groups

Randomized controlled trials are often considered the gold standard of research. In the context of prekindergarten evaluation studies, a randomized controlled trial is conducted by randomly assigning children either to receive the prekindergarten program (the treatment group) or to participate in a control group. The skills of both groups can then be measured at variable intervals during and after the program, even many years after the end of the prekindergarten program. The relation of program quality to participants' outcomes and trajectories of growth over time can also be investigated using this study design. Because of the random assignment of the participants in this type

of study, a randomized controlled trial can provide the ability to make causal inferences about the effects of prekindergarten programs, that is, to be confident that the program directly caused the effects measured in the evaluation study.

Although the control, certainty, and ability to make causal conclusions afforded by randomized controlled trials are desirable, they are not always feasible. Difficulties implementing such studies include the necessity to deny the prekindergarten program to children assigned to be in the control group (without regard to the need of the individual children and ensuring that children in this group do not receive an equivalent prekindergarten experience through other means) and the necessity of having a large enough pool of potential participants to ensure appropriate sizes in both the treatment and control groups. In cases where randomized controlled trials are not feasible, researchers may utilize other quasi-experimental designs to answer questions about the effectiveness of the prekindergarten program being evaluated.

The most powerful type of quasi-experimental research design is regression discontinuity design, which has been shown to provide the strongest evidence for treatment effects for nonexperimental approaches. When applied to prekindergarten evaluations, this design utilizes a natural experiment based on the age requirement for kindergarten to compare two groups of children: the untreated group (children entering the prekindergarten program at the time of the study who are not yet eligible for kindergarten) and the treated group (children who completed the prekindergarten program and are entering kindergarten at the time of the study). Because both groups of children qualified and were selected to participate in the prekindergarten program, the two groups are equivalent on many important characteristics; the only difference is whether the child's birth date falls before or after the cutoff for kindergarten eligibility. The skills of the participating children are then plotted against the distance of their birthdates from the birth date cutoff (up to 180 days before the cutoff for the untreated group and up to 180 days after the cutoff for the treated group). A jump, or discontinuity, at

the point of the birth date cutoff indicates the effect of the prekindergarten program.

PRENATAL MENTAL HEALTH

Based on early development indices, one-quarter of children enter school with some form of developmental delay (Hertzman, 2009). While many influences impact a child's development, research from the Avon Longitudinal Study of Parents and Children (ALSPAC) in the United Kingdom suggests that among children with suboptimal development, the main contributing factor in 10% to 15% of these children is poor prenatal maternal mental health (Glover, 2014). Thus, when considering the benefits of early intervention and possible approaches to prevention of child development problems, strong evidence from more than two decades of research studying children and their mothers from pregnancy to adolescence indicates that improving maternal prenatal mental health is

likely to improve child health and development. While there has been little research to date on whether intervention aimed at prenatal maternal mental health improves child outcomes (Kingston et al., 2014; O'Connor, Monk, & Fitelson, 2014), recent research provides promising evidence that improving mental health in pregnancy improves infant development (Milgrom et al., 2015).

Mechanisms Linking Prenatal Psychological Distress to Child Outcomes

A long history of evidence from animal studies shows clear evidence of a link between prenatal stress and poor offspring outcomes (O'Connor et al., 2014; Weinstock, 2008). Whether similar conclusions could be drawn in humans in terms of whether prenatal stress could have an adverse effect on child outcomes remained a subject of debate for many years. In 1995, physician and epidemiologist David Barker introduced the fetal origins hypothesis to explain why adults who had been born small for gestational age had higher risk of certain diseases, such as heart disease. He proposed that adverse intrauterine influences could play a role in the development of chronic disease, and this prompted a paradigm shift that acknowledged that neurobiological development is influenced by prenatal exposures (O'Connor et al., 2014). Over the past 2 decades a large body of evidence has developed providing empirical support for the association between intrauterine influences and a large array of suboptimal child and adult health outcomes, including heart disease, diabetes, mental illness, and developmental delays (Barker & Thornburg, 2013). With respect to child outcomes, some evidence now exists for the effect of stress- and anxiety-related increases in glucocorticoids on the developing fetal brain, including DNA methylation that influences gene expression (Moisiadis & Matthews, 2014). Indeed, a 2014 study by Lei Cao-Lei and colleagues was the first to show that prenatal stress has a lasting "DNA methylation signature" (Cao-Lei et al., 2014). In this study, 8-year-old

children of women who experienced stress during the major ice storm in Quebec in 1998 had genome changes in the form of DNA methylation in the regions related to immune function, compared with children whose mothers did not experience that stress. These changes to the genome may be responsible for long-term neurological and developmental outcomes in children of mothers who experience stress or anxiety during pregnancy. A 2015 study by Karen Lillycrop and colleagues using data from the longitudinal United Kingdom Southampton Women's Survey showed evidence of this, demonstrating that DNA methylation at birth was related to child neuropsychological outcomes (IQ and executive memory function) in 4- and 7-year-old children. This study provides "support for a role of epigenetic processes in mediating the long-term consequences of early life environment on cognitive development" (Lillycrop et al., 2015, p. 1).

Impact of Prenatal Psychological Distress on Child Development

Infant Development

In 2012, a systematic review of more than two decades of research from longitudinal studies by Dawn Kingston and colleagues concluded that there is some evidence that prenatal psychological distress (defined as any form of mental health problem during pregnancy) is associated with suboptimal cognitive, behavioral, and psychomotor development in infants from birth to 12 months of age (Kingston et al., 2012). In this review, stress and anxiety were the main forms of psychological distress related to poor infant outcomes. Although prevalence rates were rarely reported by individual studies in this review, infants of mothers with anxiety during pregnancy had rates of psychomotor (30%) and cognitive delay (25%) that were two to three times greater than infants of nonanxious mothers (psychomotor, 14%; cognitive, 7%). Interestingly, no studies assessed the effect of prenatal distress on socio-emotional development.

Toddler Development

A recent systematic review compiled evidence on the association between prenatal and postnatal psychological distress and cognitive development in children ages 13 to 36 months (Kingston, 2015). Among eight studies included in the review that focused on prenatal distress, seven studies showed a significant, medium-size effect of prenatal distress on poor cognitive development. In the single study that reported prevalence rates, 22% of children born to mothers with prenatal anxiety had cognitive delay compared with 6% of those whose mothers were without prenatal anxiety (Brouwers, van Baar, & Pop, 2001). A comprehensive review of 25 studies examining the influence of prenatal psychological distress on several domains of toddler development demonstrated a significant relationship between prenatal distress and development and behavior, with limited evidence of socioemotional and psychomotor development (Kingston, 2011).

School-Age Child Development

Looking at specific forms of behavioral problems, a study based on the prominent ALSPAC in the United Kingdom showed that rates of hyperactivity and conduct problems were over 85% and 62% (respectively) greater in children whose mothers experienced prenatal anxiety in the third trimester compared with those who did not (O'Connor et al., 2003). These findings were found after controlling for the influence of postnatal depression and anxiety indicating that prenatal distress has a unique role to play that is distinctive from postpartum mental health influences. While the evidence is limited in that it is based on only two studies, research using data from two prominent birth cohorts—the ALSPAC (O'Connor et al., 2003) and the Raine cohort (Robinson et al., 2008)—found small- and medium-size effects of prenatal stress and anxiety on socioemotional development in school-age children.

Do Sensitive Periods Exist?

Research to date cannot provide a definitive answer about whether children of mothers who

experience stress, depression, or anxiety in a particular trimester are more at risk for poor outcomes compared with a similar exposure in another trimester (Kingston, 2011; Kingston et al., 2012; O'Connor et al., 2014). While it would be beneficial to understand whether such “sensitive periods” for prenatal mental illness exist, in reality, epidemiologic studies show that results from prenatal mental health problems are stable. That is, their severity tends to be consistent across the prenatal and postnatal period (except for women with high severity, who tend to worsen over time if no help is afforded them) (Giallo et al., 2015; Woolhouse, Gartland, Mensah, & Brown, 2015), and women with prenatal and postnatal distress are more likely to have also experienced symptoms pre-pregnancy (Milgrom et al., 2008). This evidence suggests that a focus on women's mental health pre-pregnancy is the best approach to optimizing child outcomes.

Impact of Chronic Mental Health Problems

There is a paucity of research examining whether chronic mental health symptoms have a greater impact on child outcomes compared with symptoms that are experienced only briefly. While one study demonstrated that children born to women with chronic depression (e.g., beginning in pregnancy and extending into the postnatal period) were at greater risk for behavior problems and lower vocabulary scores (Brennan et al., 2000) compared with children whose mothers experienced brief bouts of depression, data from the ALSPAC study did not find that children were more affected with emotional/behavioral problems if their mothers had both prenatal anxiety and postnatal depression (O'Connor et al., 2002). However, substantial evidence published independently from two prominent birth cohorts—the Longitudinal Study of Australian Children and the EDEN birth cohort—suggests that persistent depressive symptoms of subclinical, intermediate, or high severity are associated with behavioral and socioemotional problems in 4- and 5-year-old children, compared with children whose mothers did not have persistent symptoms.

Clinical and Subclinical Severity

Early research suggested that the effects of prenatal stress, depression, and anxiety on child development outcomes and mental health may be limited to women with severe symptoms. However, recent studies have found a “dose response effect,” where the greater the severity of the symptoms, the greater the risk of poor developmental outcomes (O'Connor et al., 2014). This was perhaps most strikingly illustrated in a recent longitudinal cohort study from Australia that showed that rates of socioemotional and behavioral problems in 4-year-old children were 7% in women with no prenatal depression, 19% in those with subclinical depression, and 24% in those with the highest severity of depression (Giallo et al., 2015). As noted by Thomas O'Connor and colleagues (2014), this evidence of an adverse effect of even subclinical depression or anxiety highlights the need to detect and treat mental health problems during pregnancy and broadens the public health concern beyond women with clinically diagnosed mental health problems.

Conclusion

A growing body of evidence suggests a clear association between prenatal maternal mental health and suboptimal child outcomes. Despite recommendations from the National Institute for Health and Care Excellence in the United Kingdom and the American College of Obstetricians and Gynecologists, among others, mental health is not assessed or treated as a part of routine prenatal care. Indeed, current prenatal care tends to focus on physical health (e.g., healthy diet and weight gain) and preparation for delivery, with a notable absence of discussion surrounding mental health (O'Connor et al., 2014). However, convincing evidence linking prenatal maternal distress to poor child outcomes substantiates the need for mental health screening and treatment to be offered routinely to all pregnant women.

PREPARING EARLY CHILDHOOD TEACHERS TO IMPLEMENT DIGITAL MEDIA

Living and learning in the digital age raises important questions about how early childhood teachers are prepared, and how prepared teacher educators and professional development providers are, to integrate digital technology and media into teaching practices and teacher preparation. This entry explores the connection between the foundational knowledge and experiences early childhood educators gain through traditional preservice and in-service training and what else they need to know and be able to do in the digital age. Implications for digital age teacher preparation and teacher educators are identified and explored.

Children are born ready to learn, and the experiences they have in early childhood influence their development and learning across the life span. Early childhood educators, in formal and informal settings, share a responsibility with parents and families for the healthy growth, development, and learning of young children.

Traditionally, the preparation of early childhood educators has been based on what is known about how children grow, develop, and learn. Teacher preparation focuses on the core knowledge educators need to know, the practical experiences they need to have, and the competencies they must demonstrate for providing high-quality early care and education that promotes children's health, development, and learning.

Setting the Context for Teacher Preparation in the Digital Age

Digital technologies including smartphones, mobile devices, multitouch screens, and tablets have quickly become ubiquitous at home and in the workplace. These powerful tools have changed the ways in which adults connect, interact, communicate, collaborate, access information, learn,

and create. These same tools are already in the competent hands of very young children.

Teaching and learning in the digital age means that all adults who work with or on behalf of young children, parents, and families need to understand the if, when, where, how, and why of effective technology integration. This includes educators and the teacher educators, professional development providers, trainers, and program administrators who prepare them.

Effective digital age teacher preparation needs to include thoughtful integration of technology tools and methods into preservice, in-service, professional development, and continuing education. Six ways that educators can use technology personally and professionally need to be included in teacher preparation programs:

1. Tools for personal use, everyday living, and connecting with family and friends
2. Tools and methods for teacher preparation including online learning, webinars, online resources, and communities of practice
3. Tools for classroom teachers and teaching including documentation, assessment, curriculum planning, record keeping, and more
4. Tools to use with children for teaching and learning
5. Tools for strengthening the home-school connection and enhancing family engagement
6. Tools for professional communicating, collaborating, and connecting

Early childhood educators in preservice and professional development need in-depth, hands-on technology experiences that build competency and confidence. Access to the latest technology and interactive media for adult learning and for supporting health, development, and learning of young children and opportunities to be playful and create with these tools are needed so that young children can experience technology and digital media as playful, open-ended, and powerful tools for learning and creating.

What Digital Age Educators Need to Know and Be Able to Do

Early childhood educators have always needed positive attitudes toward children, parents, and families, core knowledge, essential experiences, and competencies leading to fluency in the principles and practices that support young children's health, development, and learning—Early Childhood Literacy. In the digital age, educators also need positive attitudes, knowledge, experiences, and skills leading to fluency with technology and digital media as tools for teaching and learning—Digital Media Literacy.

Foundational knowledge of child development theory, early learning, and the influence of family, culture, language, and community guide the selection, use, integration, and evaluation of appropriate technology tools and digital media for young children, just as it supports the choices educators make every day about all other tools for learning in the classroom.

Early childhood educators are not unprepared to integrate technology and to practice the appropriate and intentional use of technology. Educators should consider the integration of technology and digital media into early childhood classrooms and settings in the context of what they already know and apply every day to decisions about what tool is most appropriate for an individual child, at a particular time, for a particular learning goal.

Teachers need to begin with what they know about child development theory and how young children learn. While the most influential child development theories and theorists predate the digital age, they provide foundational knowledge for the selection, use, and integration of technology with young children today. Teachers can look to the pedagogical and theoretical approaches of Maria Montessori, Jean Piaget, Erik Erikson, Lev Vygotsky, and others for guidance in the design and development of curriculum, activities, and interactions that integrate technology and support children's health, development, and learning.

In addition to these theoretical underpinnings, educators should turn to the Developmentally

Appropriate Practices framework from the National Association for the Education of Young Children (NAEYC) and to the NAEYC and Fred Rogers Center joint position statement on *Technology and Interactive Media as Tools in Early Childhood Programs Serving Children From Birth Through Age 8*. The technology position statement, grounded in developmentally appropriate practice and more than 40 years of research on children's television viewing, defines how appropriate and intentional use of technology and media with young children can support learning and development.

Educators who combine core knowledge in child development theory, developmentally appropriate practices, a deep understanding of diversity and cultural competence, and an appreciation of the influence of family, culture, community, and social contexts have a solid framework for making mindful choices about technology with young children. As key decision makers in integrating technology and media, educators need to connect child development, early learning, and digital media.

Early childhood educators are not unprepared, but will remain ill prepared or underprepared as analog adults in the digital world of young children without teacher preparation and professional development experiences that connect what they know with what is known about effective, appropriate, and intentional selection, use, and integration of technology tools for learning in the early years.

What Is Known and Why It Matters to Early Childhood Educators

The body of research and literature around children's television use has developed over more than 40 years. What has been learned about young children and screen media informs a digital age approach to teaching and teacher preparation by identifying what is known and why it matters to inform classroom practices that integrate technology tools into teaching and learning. More research on new digital tools, multitouch screens, and interactive media is needed to better understand the impact of these technologies on children's health, development, and learning. However, since these

tools are already in the hands of young children, it is important to understand what is known and what matters, including the following:

- digital media literacy,
- concerns about technology use,
- early childhood “essentials,”
- families,
- relationships,
- joint engagement, and
- content and context.

Digital media literacy matters to adults who work with or on behalf of young children and is essential for 21st century early childhood educators and for the teacher educators who prepare them.

Concerns about technology use and very young children need to be thoughtfully considered including the amount and kinds of screen time, passive media use, exposure to inappropriate content and commercial messages, the displacement of developmentally essential materials and activities, social isolation, interrupted adult–child relationships, less outdoor time and physical activity, childhood obesity, sleep disruptions, and other health concerns.

The goal of technology integration in classrooms and early childhood settings is not to displace or replace essential activities and experiences that support creativity, curiosity, open-ended exploration, unstructured play, hands-on materials, outdoor play, and nature within a whole-child approach. When technology is integrated appropriately and intentionally, the goal is to enhance and expand essential activities and experiences and to provide universal access to powerful tools for learning in new ways and for all children.

Early childhood educators have long understood that families matter. In the digital age, how families access and use media in the home also matters. How children use media at home reflects their interests and needs and is strongly influenced by family needs, backgrounds, languages, cultures, communities, attitudes toward technology, access to technology and a broadband connection, the media habits of the adults in the home, and the family media ecology.

Early childhood educators know that young children learn best in the context of interactions and relationships with tuned-in, responsive, and caring adults at home and in early childhood settings. Appropriate and intentional use of technology to strengthen relationships, encourage prosocial behaviors, and promote social-emotional development supports children’s development and learning. Educators know that adult–child interactions are key to language learning. In the digital age, opportunities for joint engagement with media provide new opportunities for using media together to deepen learning and strengthen relationships.

The quality of content and the context of technology and media use in early childhood settings also matter. With quality content, “what children watch” on screens is more important than “how much” or “how long” they watch. Digital age educators and parents need a new way of defining screen time that takes into account the affordances of the device, active learning, the interactive media, and the appropriateness of the content and learning opportunities for the child.

Where, when, how, and with whom are important issues to consider in the context of technology and media use in the classroom or other early childhood setting. Early childhood educators know that children learn best in active environments when they are engaged in meaningful, interactive, and social contexts, and the same considerations need to inform instructional practices and technology use.

Understanding what is known and why it matters for teacher preparation and for teaching practices in early childhood settings leads to implications for digital-age preservice and in-service teacher preparation and professional development.

A 21st-Century Context for Teacher Preparation

Digital media literacy is an essential literacy for early childhood educators for 21st-century teaching and learning. Teacher educators need to integrate digital media literacy across the continuum of teacher preparation and professional development

and provide early childhood educators with hands-on opportunities for playful exploration, to use technology to learn how best to use technology, and to learn with and from other educators in “tech playgroups” or in online communities.

Early childhood teachers and teacher educators need the following:

- technology knowledge, skills, and experiences;
- digital media literacy in the context of early childhood teaching;
- tools and methods for teaching with technology;
- hands-on opportunities to play with technology;
- examples of effective technology integration in early childhood;
- ongoing professional development;
- communities of practice and interest; and
- research about effective practices.

Making connections between theory, guidelines, and best practices ensures that technology choices are appropriate and effective. Taking time to play and explore digital tools enhances appropriate and intentional use of technology to support children’s learning and development. Gaining digital media literacy enhances educators’ attitudes, knowledge, experiences, and competencies to create empowering and valuable learning experiences for young children.

The digital age is here. Digital media literacy is an essential new literacy for those who teach the teachers, and those who teach young children. Early childhood educators in the 21st century have a very real responsibility to gain the technology knowledge, experiences, and competencies needed in their work and to enhance their interactions with parents and young children.

These new tools hold great promise for teaching and learning, but only when they are used effectively, appropriately, and intentionally. The knowledge and experience needed to select, use, integrate, and evaluate technology and interactive media as tools in early childhood settings is at the heart of what it means to be a contemporary educator and how best to prepare teachers in the digital age.

PRESCHOOL

Early childhood is an important developmental period for children as they learn and acquire skills that will eventually aid them in school. It is also a time that marks great variability in the children’s experiences because some children stay

at home with their families, others attend private child care programs, and some attend public preschool programs such as state-funded programs or the federally funded Head Start. Across these sites, children's experiences often correspond simply because of their similarity in ages and general developmental modicums. However, depending upon the means through which they are educated on a daily basis, children do have unique experiences. This entry focuses specifically on *preschool*, examining how the term has come to be defined, the history of preschool programs, and what they offer children in the 21st century.

The History of Preschool Programs

Preschool can be defined as the period of time in a child's life that precedes attendance at elementary school. In the current era, preschool tends to refer not only to a developmental period for children but also to an educational establishment that offers early childhood education. It is also sometimes referred to as nursery school, prekindergarten (pre-K), Grade 0, or preprimary school. In various parts of the world outside of the United States, the term *kindergarten* has also been used to describe educational establishments prior to elementary school. One could argue that the preschool period begins at birth, but for the purposes of this entry, *preschool* refers to an educational establishment for children ages 3 to 5, just prior to elementary school.

Preschool programs began as what is more readily known as child care, which is a center-based program primarily focused on a safe and healthy environment where children can socialize with one another. Preschool programs resemble the formerly popular child care programs in that they provide a safe and nurturing learning space for children prior to the formal schooling period. However, they have become more focused on academics over time, often requiring high-quality standards and stressing children's school readiness and educational attainment. The discourse surrounding preschool in the United States has come to be

dominated by terms such as *high quality*, *academic achievement*, and *school readiness*.

Research on the effects of preschool on children's development dates back to the 1930s and has advanced steadily with the uprising of landmark studies that began in the 1960s. Not coincidentally, these landmark studies coincided with increased numbers of women in the labor force in the late 1960s, and therefore the expanded interest in children spending time in formal settings outside of their homes. To date, an extensive body of literature finds that high-quality preschool programs for children at 3 and 4 years of age positively impact their cognitive and noncognitive development in both the short and long terms. Further, benefit-cost studies that take into account education, crime, welfare, and labor market outcomes have found large benefits for the economy attributable to high-quality preschool programs.

Despite this research, government support for preschool is severely limited, as many children still do not have access to programs. This is largely because of the cost involved in creating a high-quality program and the tradeoff between creating high-quality programs that serve fewer children or providing access for more children that perhaps compromises program quality. The tension between access and quality is ongoing.

The Current State of Preschool in the United States

In 2014, the Education Commission of the States reported that 40 states invested in preschool programs serving approximately 1.3 million 3- and 4-year-old children. Programs vary in the length (full day versus partial day) and frequency (5 days per week versus a couple of days per week) that they offer to children. They also vary in the number of standards that they uphold as well as the population of children they serve. For instance, some programs serve specific income groups (i.e., New Jersey) while other programs are universal and serve all children in the state (i.e., Oklahoma). There are also various combinations of funding across states: for example, some programs partner

with Head Start, others utilize child care subsidies, and others rely strictly on state dollars.

Preschool Program Quality

A quality preschool program includes several components that consider children and their families, classroom environments in terms of visual space and materials, cleanliness and safety, and interactions between teachers and children and among children, as well as accommodations for parents and program staff members. Basic preschool standards that serve as proxies for quality include comprehensive early learning standards, teacher education and training, assistant teacher education, class size and ratio, teacher in-service, meals, monitoring, and referral and support services.

The discourse surrounding preschool quality has shifted over time to one characterized by a process-oriented focus, emphasizing what occurs in the classroom. This marks a clear divergence from the proxies of quality mentioned above that were so heavily attended to in the past. In general, the notion of preschool quality refers to a safe and engaging environment that prepares children for kindergarten, with teachers whose professional backgrounds allow them to have supportive relationships with children. Quality programs also have educated teachers who can foster children's autonomy and productivity while maintaining order in the classroom. There is also frequent communication between parents and teachers, along with expectations for growth of teaching staff.

At a more detailed level, quality preschool programs are often guided by two standardized observational measures: the Classroom Assessment Scoring System (CLASS) and the Early Childhood Environment Rating Scale (ECERS). These two measures are used widely in programs to guide the structure of the environment and the interactions that occur.

The ECERS is used to guide the space and furnishings and materials that define the classroom, as well as personal care routines, language and reasoning, activities, and basic interactions that take place. In addition, the ECERS considers the

structure of the program and provisions for parents and staff.

A preschool classroom with high quality for space and furnishings has an array of gross motor equipment and accessible, child-size toilets, sinks, tables, and chairs. It also has soft furnishings and soft toys, many materials (for art, music, dramatic play, math, and science), books, and displays for children to engage with. The environment is also cleaned daily, with age-appropriate toys and furniture in good repair.

In addition to space and furnishing accommodations, children are greeted and helped to become involved in activities. They are also allowed to nap as needed, and when necessary, they receive extra assistance with emotional or academic needs. Behavior expectations are made clear to children, and transitions from one activity to the next are made quickly to minimize waiting and down time. Children are also affirmed, encouraged, and scaffolded to explore independently.

High-quality preschool programs also provide separate bathrooms and a lounge area for teachers, as well as well-equipped office spaces and resources, and support for taking courses or attending training sessions. Paid sick and vacation leave for teachers are also provided in high-quality programs. Parents are informed in detail about the program prior to enrolling their children and there is frequent communication between parents and teachers. Parents are also referred to professional services as necessary and involved in classroom activities as a regular part of a high-quality program.

The CLASS focuses more on the nuances of the emotional and instructional interactions that take place between teachers and children and among children, to guide the level of program quality. Specifically, the CLASS measures how teachers help children develop warm, supportive relationships with teachers and peers; children's enjoyment of and excitement about learning; their motivation to engage in learning activities; their feelings of comfort in the classroom; their willingness to accept academic and social challenges; and whether levels of autonomy are appropriate. In addition, CLASS is used to measure the degree to which

teachers help children learn to solve problems, reason, and think; use feedback to expand and deepen skills and knowledge; and develop more complex language skills. Lastly, it is used to assess how teachers assist children in developing skills that will help them regulate their own behavior, get the most out of each school day, and maintain interest in learning activities.

As with any measure of program quality, a variety of assumptions underlie the items that comprise the ECERS and the CLASS. Even so, these two measures, in conjunction with a number of other measures, are widely accepted and have been extensively adopted in a number of states throughout the United States as part of quality and rating improvement systems (QRISs). A QRIS is an organized way to assess, improve, and communicate the quality of early childhood programs. Essentially, it is a system that considers various criteria in assigning a rating to each participating program. Typically, three to five levels of quality are designated based on the degree to which programs are meeting their predetermined standards of quality.

Programs that participate in QRISs receive supports (e.g., technical assistance on creating quality improvement plans, or professional development to enhance teacher knowledge and skills). They are also often given financial incentives to maintain higher quality ratings. Simple, easy-to-understand QRIS ratings enable parents to become savvy consumers of preschool programs for their children. Clear ratings also promote accountability, provide an avenue for policy makers to improve preschool quality, and ultimately promote the healthy development of children.

QRISs are becoming increasingly conspicuous in state preschool programs, as forms of accountability systems. As mentioned previously, more than 40 states now have some form of state-funded preschool program, and these programs vary in terms of the populations they serve and the characteristics of the programs. For instance, some programs seek to serve every child in a particular state (e.g., Oklahoma), while others are targeted programs and serve families that fall under a particular income level.

Further, there are many efforts currently under way to provide high-quality preschool programs for a greater number of children. In 2014, 18 states were awarded federal grants to develop or expand preschool access. Five of these states had either very small or no preschool programs at the time of the application and were awarded funds to develop programs for the first time. The other 13 states were awarded funds to expand existing programs with the aim of increasing access to high-quality preschool.

As programs are developed and expanded, the cost of implementing particular standards will have to be weighed against the goal of large-scale access. For instance, a class size of 15 students may be preferred, but a class size of 20 students would allow access to many more children. Similar considerations must be weighed in relation to salaries. While it may be preferable to pay larger salaries to teachers with superior qualifications, there is a trade-off between serving more children with less qualified teachers or fewer children with better qualified teachers.

Few state-funded preschool education programs existed prior to the 1990s. The rapid growth since the 1990s has been a crucial element in closing the equity gap throughout the United States, and the benefits of preschool education for children are rarely contested in the current era. However, there are fiscal challenges in terms of the trade-off between using available funds for *either* more slots *or* higher standards. Given the present focus on preschool in light of the research on its value, it is plausible that high-quality state preschool will eventually be accessible to every 3- and 4-year-old nationwide, as has been the case for elementary school for many years.

PRESCHOOL ADMINISTRATION

Preschool administration refers to the oversight and management of both the adult work environment and the daily experiences and interactions of young children in early childhood education settings, for example, preschools, child care centers, and nursery schools. Administration of programs for young children is a critical element of early childhood education because the way a program is managed has a large impact on the overall quality of the environment for the children in its care, children's families, and the staff who work with children and families on a daily basis. The following entry offers an explanation of the role of administrators in preschool programs and

a discussion of the importance of this administration to global quality.

Preschool settings can be either nonprofit or for profit, a full- or half-day program, and contained in a child care center, family home program, nursery school, laboratory preschool, or other variations of preschool settings. Regardless of the type, the administrator is responsible for overseeing all aspects of the program. Preschool administrators, often referred to as directors, managers, or principals, are responsible for hiring and firing of staff, maintenance of current records for children (e.g., immunizations) and staff (e.g., criminal background checks, immunization records, training hours completed); adherence to a budget (and often development of that budget, as well); accounts payable and receivable; the nutritional quality of the program's menus; the overall quality of the program; marketing the program; collection of parent fees; family involvement; parent communication; evaluation of staff performance; provision of professional and staff development opportunities; collaboration with state licensing agencies; adherence to all state regulations and requirements for operation; collaboration with state and federal subsidy programs (when applicable); establishment and oversight of program policies on health, safety, nutrition, employment, parent responsibilities to the program, staff expectations, and child behavior; oversight of all program operations; risk management; evaluation of program operations, procedures, policies, and quality; program planning; supporting expected child behaviors and intervening with challenging behavior; and anything else that may arise in the course of daily events in a preschool setting. Preschool administrators are ultimately responsible for everything that occurs in the program that they oversee.

One of the most important responsibilities of a preschool administrator is knowledge of and adherence to all state requirements for programs for young children. Each state in the United States has minimum standards that programs must adhere to in order to remain in operation, and wide variations exist in the stringency and oversight of these standards, resulting in variations in

quality levels across programs and states. These requirements typically cover issues related to cleanliness, safety, group sizes, teacher–child ratios, physical space, playground equipment and safety, nutritional requirements, teacher education and ongoing training requirements, criminal background checks for staff, immunization requirements for children, food safety, transportation of children, and maintenance of program records, in addition to many other requirements, all varying by state. Partly due to these variations among states and partly due to a desire to focus on program aspects that deal more directly with the types and varieties of activities and interactions that children experience while in preschool settings, professional organizations have developed voluntary accreditation opportunities. These accreditation programs offer an additional responsibility to program administrators who voluntarily enter into the accreditation process with regard to detailed self-studies, detailed documentation of program policies and procedures, external reviews of program quality, and ongoing reaccreditation processes once accreditation is awarded. While program administrators are not required to participate in these accreditation opportunities, those that do and are successful in attaining it may have increased responsibilities in terms of program operations and policy oversight, as well as reporting to the accrediting body. It is generally agreed that accredited programs are more likely to offer higher quality programming than nonaccredited programs, and a wealth of research supports the conclusion that higher quality early childhood programs lead to better developmental outcomes for children.

While preschool administrators spend less time in direct interaction with children in these settings, they are ultimately responsible for the daily experiences and interactions of children. Preschool administrators are responsible for ensuring that teachers meet educational requirements of the program (and state), receive the required amount of training hours per year, develop age-appropriate lesson plans, promote developmentally appropriate practices that provide a wide variety of types

of activities for children that include hands-on learning, free play, child–child interactions, and teacher–child interactions.

In conclusion, preschool administration refers to the day-to-day oversight and operation of programs for young children. Preschool administrators are responsible for all aspects of the programs that they oversee, and the administrator's leadership, management, and oversight is an important component of overall program quality.

PRESCHOOL ROOMS

The preschool environment has a profound effect on emotional well-being and can either enhance or detract from learning. Large-scale studies and mega-analysis show that high-quality preschools can provide both short- and long-term benefits for

children's socioemotional and cognitive development and their future academic success. Although the effect of high-quality preschool does appear to decrease over time, there is a lasting effect on cognitive and social outcomes and school progress.

However, large-scale studies also indicate that many programs are not high quality and might actually cause children harm. Due to the high percentage of children in preschool programs, the quality of care they receive can have large consequences not only for the child and family but also for society. For example, according to the National Center for Education Statistics, 44% of 3-year-old, 66% of 4-year-old, and 85% of 5-year-old U.S. children attended a preprimary program in 2012.

Preschool rooms are designed for children between the ages of 3 and 5, before they begin kindergarten. However, where these programs are housed and the structure of the programs varies. Programs may be designed to house a single age level or be designed for a multiage group. They may be housed in Head Start programs, public schools, or other public and private settings. Preschool rooms might be part-day or full-day programs. This entry provides information about two very important aspects that determine a preschool's quality, the emotional environment and the physical environment, including the role of the teacher within the environment.

Emotionally Supportive Environment

Emotionally supportive teaching is the foundation for quality care. Emotionally supportive teachers are in tune with developmental progressions, children's individual needs and interests, and the cultures and communities in which children reside. They use this information to develop positive relationships with each child and to offer consistent, respectful emotional, social, and academic support.

When teachers are consistently emotionally supportive, research shows that children feel safe, positive behavior increases, and there is improved academic readiness resulting in higher social, math, and reading scores in later grades. Education

resiliency and work habits are also positively influenced by supportive teachers. Additionally, consistent, emotionally supportive teachers act as a buffer for children's stress helping children cope effectively with stressors. This is especially crucial because excessive stress has been found to affect the actual architecture of the brain and to have short- and long-term impacts on memory, learning, and self-regulation (the control of emotions, actions, and thinking).

To provide an emotionally supportive environment, teachers assist children to develop skills including self-regulation skills. Children who have better self-regulation skills have higher self-esteem, increased academic performance, better social skills, and the ability to handle emotions constructively. They also have better long-term outcomes in relationship to health, substance abuse, finances, and criminal behaviors.

Supportive teachers have realistic expectations for young children and view problem or mistaken behaviors as learning opportunities. They assist children to recognize and then learn to control their emotions through planned activities and teachable moments. When issues arise, they use and teach children positive guidance strategies such as conflict resolution. The environment is also designed to assist with emotional regulation, providing quiet retreat spaces, as well as soothing and active activities. For example, one child might pound on earth clay when she gets angry while another might retreat to an alone space. A child who is anxious might find comfort playing at the water table.

Skilled teachers also help children develop friendship skills. The quality of children's friendships is linked to future social, emotional, and academic outcomes. The teacher develops a classroom community where each child feels like a valuable member of a group whose members actively encourage, support, and influence each other. To develop social and friendship skills, children need abundant daily opportunities to interact while participating in learning centers, small groups, and mealtimes. They also need teachers who support them in learning skills such as how to

join and sustain play. Skilled early childhood teachers stress cooperation. Even subtle forms of competition are eliminated such as having the quietest child leave the circle first.

Additionally, effective teachers assist children to feel competent. This is done by providing the right degree of independence based on children's development, individual needs, and cultural expectations. For example, preschool children can become increasingly proficient at accomplishing self-help skills such as dressing themselves. Children might also perform classroom jobs. In some classrooms, children even lead the circle time activities. Most importantly, curriculum and activities are designed so that each child can be challenged and yet successful. Assisting children to develop competence also means that teachers provide children with challenging curriculum in each of the academic areas.

The teacher also establishes a predictable, orderly environment. The environment affects not only children's learning but also their stress level. When examining children's demographics, their individual characteristics, and the early childhood environment, researchers have found that the greatest influence on children's cortisol levels is the environment. Cortisol (a stress hormone) levels are higher in unstructured and low-quality settings. This is a concern because high cortisol levels put children at risk for poor developmental outcomes.

Rich Learning Environment

A rich learning environment is another characteristic of a quality preschool program. The way that the environment is arranged supports a particular philosophy of education. In early childhood, teachers and programs typically have a constructivist philosophy. Early childhood education has a rich history of supporting play-based learning using a constructivist approach. Children are viewed as active constructors of knowledge with the teacher assuming the role of facilitator. This view was promoted by many theorists and approaches including Maria Montessori, Lev Vygotsky, John Dewey, and Loris Malaguzzi. This view continues to be preva-

lent and is prominent in National Association for the Education of Young Children (NAEYC) position statements including the Position Statement on Developmentally Appropriate Practice. Play is viewed as the perfect medium for children to actively construct knowledge because as children play, they engage in integrated, authentic learning at their ideal level of development. Additionally, while they interact with others, their learning is often scaffolded, or supported, by a more competent peer. Further, during sociodramatic play (pretend play with others), they use abstract thought as they separate meaning from an object, practice self-regulation skills to keep the script alive, and learn social skills.

A primary way that children engage in play-based learning is through using learning centers. Learning centers are self-contained areas with a variety of hands-on materials organized around a curriculum area or topic. A preschool room typically contains dramatic play, creative art, literacy (reading, writing, and listening), music, sensory, manipulative, science, math, and block and construction centers. Technology is most effective when it is used as a tool to enrich the curriculum. Therefore, effective programs infuse technology throughout the learning space. For example, a tablet computer might be placed in the science center, allowing children to watch a video clip related to their current topic of study.

Each center enhances unique knowledge, skills, and dispositions. For example, as children use blocks they have the opportunity to gain mathematical knowledge. Research has shown a correlation between children's preschool block-building ability and their math abilities in middle and high school. Children who are more proficient block builders score higher on math achievement tests, take more advanced math, and have better grades in math even when factoring in gender, intelligence, and social class.

While using learning centers, children should have choices of what centers to engage in, what materials to use, and whether to work alone or with others. When the centers are well developed, this allows children to choose centers and materials

that match their interests and development. Studies show that when children have choices of activities they are more self-directed, have less disruptive behavior, and are more engaged in tasks. Within the classroom, spaces are developed for children to work individually, in pairs, or in small groups and to gather as a large group.

Effective classrooms are specifically designed to allow children to engage in deep, rich play. To limit disruptions between the learning centers, the centers are grouped into quiet and active centers. Centers that can be used in a reciprocal way to enrich play are placed next to each other. For example, children may build a bus in the block area and then use clothing from the dramatic play center to enhance their play.

Well-defined boundaries between centers also increase the level of play. The boundaries help control traffic, keep activities from interfering with each other, and assist children in retaining focus. Boundaries might be created with shelving and furniture, with portable low screens, or by hanging sheer material from the ceiling. Research reveals that children are more deeply engaged in their activities and are less distracted when there are well-defined boundaries. In addition, children display more appropriate behavior, positive interactions, and cooperation resulting in teachers who are less controlling and more engaged in learning activities.

Design experts recommend that there be a minimum of 50 square feet of space per child. High density levels, or crowdedness, negatively affects children's cortisol levels, social interactions, attention span, and achievement. Crowding is especially detrimental for children who have special needs or who experience crowded environments at home. Teachers also need to ensure that all the areas of the classroom are being effectively used. For example, the large group space might also be used as the music and movement center during center time.

Alone areas or retreat spaces are also a critical aspect of the environment. Many children spend nine hours a day in an early childhood environment and feel the need to occasionally escape the large group. Retreat areas are most effective when

they are small and encapsulated. The space allows children to remove themselves from the group while still witnessing the world around them. For safety reasons, spaces are designed so that adults can easily monitor them. For example, using sheer curtains or open tops allows children to feel enclosed while also allowing supervision. Retreat areas might be created under a loft or teacher's desk or in a mirrored wooden box. Children might help create a retreat area by making an igloo from gallon milk cartons or a painted refrigerator box. The retreat area houses materials that are calming for the children in the group such as a tape player with nature sounds, books, or art materials. When retreat areas are available, children interact more with peers, engage in less wandering behavior, are less aggressive, and display enhanced cognitive development.

Storage is another aspect that is important in a well-designed room. Storage includes personal storage for children and teachers, storage needed to replenish and rotate materials, and storage for children's ongoing projects. Having appropriate storage can save money, time, and frustration.

Choosing and Displaying Materials

Learning materials for preschool classrooms need to be developmentally appropriate, designed for individuals and for the age group, interesting to the children, and culturally relevant. For example, a study that looked at the cultural relevance of materials found that when non-school-attending children in a third-world agricultural community used seeds for a math task, they outperformed a group of children from the United States. However, when colored disks were used for the task, the children in the United States performed better.

Since children in a classroom are at a variety of developmental levels, materials need to accommodate this need. One way this is accomplished is through providing open-ended materials such as buttons to classify. This allows children who are ready to classify on one attribute such as color to do so. Children who are developmentally ready can classify using two attributes simultaneously,

such as color and shape. When closed materials are used, such as puzzles, the teacher needs to provide puzzles at a variety of levels.

In well-designed preschools, an abundance of materials is available to provide for more in-depth learning and to prevent waiting. For example, it is recommended that 100 unit blocks be available for each child using the block area. This allows children to build large, detailed buildings. As children build larger structures, they gain additional experience with concepts such as balance.

Materials also need to be examined for the affordances or opportunities that they provide. Red, yellow, and blue teddy bear counters found in many classrooms allow classification by size and color. However, a box of buttons provides numerous ways to classify. Authentic materials often provide more affordances for children. For example, many art easels produced for children are nonadjustable. However, an adult floor easel is often adjustable allowing for very large sheets of paper. How the activity is designed can also affect the affordances. For example, there are more opportunities for learning when color-coded music is added to the music keyboard by coding the eight groups of keys on a piano keyboard with eight different colors.

How materials are displayed can also affect learning. When materials are well organized and displayed in an attractive, aesthetic way they are easier to locate and more interesting to use. In high-quality programs the emphasis is placed on the materials, with neutral color containers and shelving. Materials are readily available and accessible for children to use. This often entails labeling of containers, so children know where items belong. For example, farm animals and zoo animals might be separated in baskets allowing children to more easily find the animal they are looking for. They are also gaining classification skills as they put the animals away.

Establishing a Context for Learning

Large studies examining how children in prekindergarten programs spend their time find that children's time is nearly equally divided between

routines (including meals), center time, and teacher-directed time. Although routine times can be effective learning opportunities, research reveals that they are not typically used this way. For example, relaxed conversation at mealtime can be used to enhance children's language and social skills. High-quality programs view all times of the day as learning opportunities, including routine times.

High-quality programs provide consistent but flexible schedules. Schedules provide consistency, allow children to anticipate what to expect next, provide the opportunity for children to build self-control and self-regulation skills, and free children to focus on higher order learning. Research reveals that children experience less anxiety and have lower cortisol levels when schedules are consistent but flexible.

For children to take advantage of learning centers, they need at least an hour of center time. This allows children to deeply engage with the activity and leads to greater learning. For example, this amount of time is needed to develop an elaborate plot, choose roles and props, and enact a dramatic play scenario. Likewise, creating a clay figure or an elaborate block structure takes time. Research shows that frequent scheduling changes, on the other hand, decrease children's internal motivation, reduce attention spans, and create an increased dependency on teachers.

Role of the Teacher

In addition to being emotionally supportive, preschool teachers are curriculum planners and environmental designers. As environmental designers, they not only set up the initial space but carefully observe, changing centers and materials to deepen children's learning. For example, in one program children became interested in collecting bugs in the play yard. Their teacher changed the science center to reflect this interest, adding magnifying jars and glasses to closely examine bugs, materials to create bug habitats, and books and short YouTube videos to learn more about bugs.

Although children learn through play with no teacher involvement, research shows that they

learn more when the teacher is judiciously involved supporting their play. This includes observing, scaffolding learning, supporting peer interactions, acknowledging children, assisting in the avoidance of risks, and documenting learning. When scaffolding learning, teachers might ask open-ended questions, provide additional information and materials, model new vocabulary, discuss concepts, or be a play partner.

Learning is also more effective when teachers assist the children to synthesize their learning. For example, the teacher who created the bug center had large and small group times where she facilitated discussions about how to care for the bugs and what the children were learning about bugs as they used the various resources.

PRESERVICE TEACHER PREPARATION

Preservice teacher preparation is the process of educating students with regard to the knowledge, skills, and dispositions needed to become teachers. Preservice teacher preparation is necessary because learning to teach is not a self-actualizing occurrence from the received wisdom of years observing

the profession as a student. In other words, teachers aren't simply produced from their experiences as students with addition of subject matter and teaching techniques in their college years. Preparation to teach offers a shift in thinking from past experiences as students to the perspectives of teachers. Research suggests a nuanced and complex understanding of how students become teachers. This entry discusses the practice, policy, and politics of teacher education.

Practice

The practice of preservice teacher preparation revolves around teacher knowledge, skills, and dispositions that should be targeted and how teachers obtain them.

Knowledge, Skills, and Dispositions

Preservice teachers must gain knowledge of learners, subject matter, and pedagogy. Knowledge of learners can include human growth and development, culture, and personal motivation. Subject matter is typically divided into branches of literacy, mathematics, science, and social studies. Knowledge of teaching can include understanding of pedagogy (teaching techniques) from direct instruction (explicit teaching) to inquiry-based learning (posing questions and establishing facts) and ways to facilitate active participation of young children.

Preservice teachers should also be able to use skills. Necessary teaching skills revolve around assessment, planning, and instruction. Assessment skills often fall into two categories: formative and summative. Formative assessment includes procedures for modifying learning during the process, while summative assessment includes procedures for evaluating learning after the process. Students' formative and summative data should be used in order to make instructional decisions. Planning skills often include long-range and short-range forms. Long-range planning can include curricular mapping (pacing the criteria or standards) and long-term student goal setting. Short-range planning can include unit, weekly, and daily planning.

Effective teachers are able to take a working understanding of instructional pedagogy and put it into action.

Preservice teachers should form teaching dispositions in areas including demonstrating professionalism, establishing a fair and supportive learning environment, and promoting leadership within the classroom and school. Dispositions for professionalism include interpersonal communication capability, punctuality, and positive demeanor. Environmental dispositions include establishing and maintaining a safe learning atmosphere with respect and sensitivity to all. Dispositions for leadership include continual growth through reflection and taking action to champion student learning. Dispositions are sometimes referred to as commitments or traits.

How Teachers Are Prepared

Teaching preparation is complex. Developing the understanding of classroom life from the perspective of a teacher rather than a student is a lengthy and challenging process. Preparation also requires multiple skills because of the challenge of connecting theory with practice. Effective teacher educators model practices and provide learning experiences in a variety of ways. Practices and experiences occur in many settings: university classrooms, school classrooms, community centers, and online arenas. Preservice teachers' progress is assessed through multiple means such as testing, conferencing, and performance-based assessments such as portfolios and teaching evaluations. Different types of resources and feedback are implemented to support teacher candidates' progress. Human resources such as mentor teachers or coaches as well as professional literature and curriculum materials contribute to teacher development. Enthusiasm from teacher educators with regard to preservice teachers' progress contributes to an understanding of professionalism and commitment to the importance of effective instruction. In addition, institutional support for teacher preparation programs is necessary for worthy efforts in fostering future committed professionals.

Policy

Preservice teacher preparation policy is informed by the certification and licensure requirements of the profession, though policies are typically established by individual states. Such state requirements vary, but generally teachers are required to obtain a bachelor's degree, complete a teacher preparation program, and pass state-mandated tests in order to obtain certification and/or licensure. Preparation programs may be completed as undergraduates, graduates, or through alternative certification programs. Traditionally, teacher preparation begins with coursework and integrated field experiences with increasing responsibility for teaching and classroom routines. Traditional programs culminate in a mentored teaching experience, which is commonly referred to as an internship, student teaching, or a practicum. Alternative preservice preparation routes, however, typically allow teachers to begin classroom teaching either after minimal preparation or while fulfilling requirements for certification. Vast variations exist among teacher preparation programs.

Politics

Accountability and equity are two issues shaping the agenda of teacher preparation programs.

Accountability

The No Child Left Behind Act (NCLB), a 2001 reiteration of the Elementary and Secondary Education Act of 1965, ushered in more accountability for public education than ever before. Teacher preparation programs must instruct future teachers to be constructively critical of how current climates affect student outcomes. Also, teacher educators are responsible for teaching preservice teachers about federal policies that impact public schools and how policies change over time. At the same time, preservice teachers need to understand that they are to develop a sense of autonomy as they meet policy requirements and at the same time effectively address academic needs of increasingly diverse populations of students. Thus, teacher

preparation programs must groom and champion teachers who are able to understand the contexts in which they work, and have the knowledge, skills, and dispositions necessary for leading students to positive outcomes in the ever-changing current political climate.

Equity

American public schools represent a very broad spectrum from thriving, innovative schools to poor, failing ones. Many preservice teacher preparation programs promote social justice (equal economic, political, and social rights), in order to prepare students for the potential effects of school inequality. An awareness of achievement gaps and their origins along with an acute sense of health and child development assist in the preparation of teachers for potential learning obstacles. Preservice educator programs endeavor to teach students constructive analysis of topics surrounding school equality in order to promote learning for all.

PRETENSE

Pretense refers to actions that are nonliteral and performed in an “as if” manner. Pretense is most commonly thought of as pretend or symbolic play, but it also can refer to the act of having something stand for or represent something else. According to psychologist Greta Fein, there are five characteristics of pretense: (1) behaviors are carried out without the appropriate materials or context; (2) behaviors are not done to achieve their normal outcome; (3) inanimate objects can be acted upon as if they were animate; (4) objects or gestures can be substituted for others; and (5) the pretender can carry out an action that is usually performed by another person or object. In addition to defining pretense, many researchers have proposed theories on the function of pretense and why children spend so much time engaging in pretense (up to 6 hours a day).

Pretense is an activity most children naturally participate in and enjoy. Therefore, understanding the effect of pretense on children’s development and learning allows us to better understand how it can be used as a tool in early childhood classrooms and curricula. This entry provides information on the developmental time course of pretense, the relation between pretense and both cognitive and social development, pretense in atypically developing populations, the role of pretense in early childhood classrooms, and future research directions.

Developmental Time Course of Pretense

The developmental time course of pretense has been well documented. The first pretend actions occur around 12 to 18 months when children begin to act “as if” with objects (e.g., bringing an empty spoon to mouth). At 24 months, children begin to engage in pretend play due to their ability to understand the symbolic relation between objects and their substitutions (e.g., using a spoon as a phone) and they begin to combine object substitutions while playing. They also begin to engage in role-play by performing actions on dolls and

stuffed animals. In addition to further developing their own pretense, they begin to understand the pretend actions of others and the imaginary outcomes these actions can have. During the preschool years, children are better at reflecting on the relation between symbols and their referents and they begin to understand irony and sarcasm. In this period, children’s pretense becomes more decontextualized or distanced from reality. They begin to substitute objects that are different from the original object in function and appearance. In middle childhood, overt pretense is replaced by games with rules, although imaginative activity persists throughout the life span.

Relation Between Pretense and Cognitive Development

Pretense has benefits for children’s cognitive development. Research in this area has focused on relations between different aspects of cognitive development and pretense and whether interventions or training programs involving pretense can lead to improvements in these domains, including intelligence, language, reasoning, creativity, and executive function.

Regarding intelligence, children who engage in more pretense with others tend to have higher intellectual ability. However, few studies have found positive effects of pretense-based interventions on children’s intelligence. Similarly, children with better language ability often engage in more pretense. Relatedly, previous research has found that pretend play or fantasy materials can increase literacy in young children. There is also a relation between pretense and narrative skills. For example, children who engage in more social pretend play and who have imaginary companions tend to have better narrative skills when completing or comprehending stories. There is also research that suggests pretend play props help children comprehend and retell stories. Another domain in which fantasy or pretense contexts improve children’s cognitive abilities is reasoning. For example, 2- to 6-year-olds reason better about syllogisms that contradict their own world knowledge (e.g., fish live in trees)

when they are presented in contexts that involve imagination or pretense (e.g., on a faraway planet).

A cognitive skill that logically seems like it would be related to pretense is creativity. Creativity is measured through tasks that assess the ability to think of multiple ways to solve a problem. Divergent thinking is associated with the frequency and imaginativeness of social pretend play, even when controlling for verbal ability. The amount of pretense in early childhood can also predict creativity up to 4 years later or in adolescence. Interventions involving pretend play can improve children's creativity, but sometimes the effects are not long lasting. For example, a play intervention led to improvements in creativity immediately after, but these effects were not seen 2 to 8 months after the intervention. Therefore, it may be necessary to have follow-up sessions for this improvement to be seen long term.

Another cognitive domain related to pretense is executive function. Executive function, commonly known as self-control, refers to higher order thinking skills that guide goal-directed behavior. These skills include working memory, inhibitory control, and cognitive flexibility. Previous research has found a strong positive relation between pretense measured in the laboratory and executive function in preschoolers. Furthermore, having children complete inhibitory control tasks improves their scores on subsequent pretense measures. Additionally, children who had good imaginations or who participated in fantasy play training waited longer during a delay-of-gratification task than children who did not. Outside the lab, frequency and persistence in sociodramatic play predicted later self-regulation during cleanup time in preschool classrooms, even when controlling for age, vocabulary, and earlier self-regulation.

Relation Between Pretense and Social Development

Pretense also has benefits for children's social development, especially for their social competence, emotion regulation and understanding, and theory of mind skills. Given that engaging in

pretense with others involves understanding the actions of others and being respectful of the rules of the pretend play episode, pretense allows children the opportunity to develop their social skills. For instance, in one study, the amount of time children spent engaging in pretend play and its complexity were related to teachers' ratings of children's social competence and popularity with peers. Other findings showed that specific aspects of pretend play such as enacting roles and negotiating rules with play partners were related to 4- and 5-year-olds' popularity with peers.

Pretense is also an activity that allows children to learn more about the emotions of others and how to regulate their own emotions. However, there are mixed results on how pretense affects emotion regulation. Some studies have found a relation between children's emotion regulation and pretend play, independent of verbal ability. Others have found a relation only in certain populations, such as in girls but not boys. Furthermore, one study found that children enrolled in Head Start programs who had better interactions with peers during play exhibited better emotion regulation in the classroom. Specific aspects of pretend play can lead to greater emotional understanding. For instance, children who engaged in more pretend play with a peer demonstrated greater understanding of the emotions of others than children who engaged in less pretend play with a peer. Moreover, cognitive aspects of pretense such as incorporating and organizing fantasy and emotions during play were related to children's ability to describe their own emotions and to understand the emotions of others.

Another topic that has gained a great deal of attention is the relation between pretense and theory of mind. Theory of mind refers to the ability to understand the beliefs, desires, and emotions of others. This is especially challenging for young children to learn when their own mental states do not match those of others. According to a large body of research, there does seem to be an association between theory of mind skills and specific types of pretense. For example, children's theory of mind is related to their production of joint proposals and explicit role-play assignments in pretend play with

others, but not to solitary pretend play. In addition, pantomime (acting out actions on imaginary objects) is a type of pretense related to theory of mind. Preschoolers with imaginary companions also tend to have better theory of mind skills. Some studies have found a correlation between the mere frequency of pretend play and children's theory of mind skills, whereas others found that the quality of early social pretend play was significantly related to children's later understanding of other people's feelings and beliefs.

Pretense in Atypical Populations

Pretense appears to be universal among typically developing children, and so its absence can be cause for concern. Most of the research on pretense with atypically developing children has focused on autism spectrum disorder. This is likely due to the fact that children with autism have a deficit in pretense in addition to other domains that are closely related, such as language and executive function. Children with autism are unlikely to spontaneously engage in pretend play, and their play is generally less symbolic and more immature than the play of typically developing children. Further investigation of this pretense deficit has revealed it is a problem with generating the pretend actions on their own since they are able to produce pretense actions when prompted to do so. Several theories attempt to explain the lack of pretense in individuals with autism. For example, one theory points to the deficit in theory of mind abilities as being the culprit, whereas another theory sees executive function as central. Either way, pretense appears to be part of the constellation of social-cognitive impairments in autism.

Pretense in Early Childhood Education

Some developmental theorists, such as Jean Piaget and Lev Vygotsky, spoke to the importance of pretend play for higher order thought and for the development of self-regulation and language in early childhood. Despite these theories and research, there has been a trend in early childhood classrooms to decrease the amount of time dedicated to

play to focus more on academic activities. Although this is the case in most traditional classrooms, there are some curricula that emphasize pretense and play, such as the Tools of the Mind curriculum created by Elena Bodrova and Deborah Leong. The Tools of the Mind curriculum is based on Vygotsky's ideas about the importance of play and language for self-regulation and uses mature sociodramatic play as a key learning tool.

The Tools of the Mind curriculum has been shown to have several benefits. For example, in a few randomized controlled trials, children in kindergarten and preschool classrooms that used the Tools of the Mind curriculum had fewer behavior problems, better executive function skills, better information processing, and improvements in math, reading, and vocabulary learning. The classroom environment was also of better quality for learning and language development. This research suggests a pretend play-based curriculum can be effective in the early schooling years.

Pretense appears to be related to children's cognitive and social development and can lead to positive social and academic outcomes when incorporated into early childhood curricula. However, it is important to remember that much of the current work is correlational, and causal relations cannot currently be determined.

Future Directions

Although there is a rich literature on pretense during development, there are still some unanswered questions. For example, what are the specific aspects of play-based curricula that are important for improving children's social and academic outcomes? The interrelations among pretense, theory of mind, and executive function also need to be studied further to better understand the developmental mechanisms underlying these skills, and how best to intervene. Finally, continued investigation of the function of pretense in early childhood is needed to better understand how pretense can impact development in diverse populations.

PREVENTION SCIENCE AND EARLY EDUCATION

This entry first examines the ways in which the fetal environment, the home environment, and the social setting more generally affect the long-term development of the child. Such analysis is known as *prevention science* because it seeks to identify ways to prevent negative impacts on the child from conception onward. The entry reviews the research on the positive impact of early education and concludes with a look at the relationship between public policy and early childhood education.

Impacts of Fetal, Home, and Social Environments

Who our parents are, our health at birth, and how we live, eat, and play as young children all have an impact on our adult life. Starting at conception, the outside world gets under the skin. The environment of the developing fetus—the nutrition it receives, the pollutants, drugs and infections it is

exposed to, and the mother's overall health, well-being, and stress level—influences how genes are expressed and ultimately how the brain is formed and functions.

The newborn brain is about 25% of its approximate adult weight. By the time the child starts school, it has grown dramatically by producing billions of cells and hundreds of trillions of connections, or synapses, between these cells. Nurturing, stimulation, and nutrition interact with genetic predispositions to sculpt the architecture of the brain and its neural pathways, influencing learning, behavior, and physical and mental health over the life course.

Adversity in early childhood in the form of harsh, neglectful, or inconsistent parenting, combined with poor social demographic factors, has an impact on brain development. These can create cascading effects that manifest throughout the life cycle:

In preschoolers: aggression or withdrawal, developmental delays

In adolescents and young adults: poor academic performance; low levels of school completion; early pregnancy; mental health problems and risky behavior, including substance abuse

In adults: obesity; type 2 diabetes, cancers, and heart disease

In turn, intergenerational cycles of poor outcomes are perpetuated. Developmental neuroscience is revealing why and how these early experiences influence human development. They also tell us why it can be so difficult to alter development trajectories; for once formed, the neural connections that underpin competencies can be difficult to modify.

Educational attainment is associated with several factors including socioeconomic status, physical and mental health, and the likelihood of engaging in anti-social behavior. However, the capacity to learn in school is strongly influenced by the neural wiring that takes place in the years before schooling begins. The connections that are formed between neurons and between neural networks affect a child's ability to attend to a lesson;

to recognize patterns; to absorb, process, and retain new information; to understand what others are thinking or feeling; or simply, to grasp and conform to the norms of classroom behavior. The greater the synchrony between the subcortical and prefrontal systems in the child's brain, the more the child will thrive in a school environment. But when a child enters school with underdeveloped connections or with constrictions in these neural networks, the abilities needed to benefit from schooling can be significantly impeded.

Reducing academic gaps and their resulting long-term social inequities is dependent on improving the competencies of children before they start school. These aptitudes include language skills, cognitive abilities, and the social and emotional capacity needed to interact with peers and adults. Canadian assessments of kindergarten-age children indicate that 1 in 4 is vulnerable in at least one of the above areas of development. These differences persist and often increase during the child's school years. For example, research from the University of British Columbia links vulnerability in kindergarten to poorer performance on standardized testing in Grades 4 and 7. Other Canadian research links vulnerability in kindergarten with poor academic results, including increased grade repetition and early school leaving, at Grades 10 and 12.

The home environment has the strongest influence on children's competencies prior to school entry. Quality early education has been found to amplify benefits for all children and helps to mitigate the detrimental effects of adverse home and neighborhood environments on school readiness. Children who benefit most from participation in quality preschool, but who are the least likely to attend, are those living in families disadvantaged by poverty.

The Benefits of Early Childhood Education

Meta-analyses of 40 years of developmental research identify advantages from regular attendance in early childhood programs that persist

into adulthood. A large study of more than 3,500 children in the United Kingdom tracked participants into their teens and shows the effect size of home versus outside factors. The home environment, including parent education, the health of family members, and family income and socioeconomic factors, exerts the most influence on child outcomes. However, the strongest influencers outside the home are early education and the quality of early schooling. The effect size of preschool attendance was found to be stronger than other interventions including home visiting or parenting programs alone. Preschool could also help compensate for adverse neighborhood influences. Work from North Carolina indicates that good quality early education can compensate children for lower quality primary schooling. These studies provide important information for policy makers. While it is difficult for public policy to alter family dynamics, it does exert considerable influence over the availability and quality of preschool and primary schooling.

Early language exposure at home predicts the size of children's growing vocabulary and later verbal and literacy skills. One U.S. study found that by age 4, children in affluent families heard 30 million more words and have vocabularies that are three times larger than children in low-income families. Children with poor verbal skills at school entry are unlikely to have the process reversed by the school system. A Quebec longitudinal study reported that children's expressive language prior to school entry is the best determinant of future reading competencies.

Similar findings are reported from a New Zealand longitudinal study, *Competent Children, Competent Learners*. Children who were low achievers at age 5 were likely to remain well below the median for all reading and mathematics tests at ages 14 and 16, regardless of family socioeconomic status. The study began in 1993 with 500 children who were almost 5 years old to investigate whether early childhood education helps children become lifelong learners, and if so, how. Researchers collected data about cognitive competencies, social and communication skills,

and home and education experiences. The findings reveal the difficulty of raising low levels of performance, particularly after age 8. The study points to the value of early education programs that include high-quality interactions between children and staff, educators who join in the children's play, and a "print-saturated" environment.

A longitudinal study in Sweden found a correlation between low literacy levels in adolescence and anti-social behaviors. Although there are many explanations for this relationship, there is strong evidence that the degree of verbal exposure in the form of reading and language in early childhood has significant effects on later literacy. Talking and reading to young children are also associated with the quality of adult-child interactions.

The quality of adult interactions—how responsive adults are to the child and the quality of the nurturance the child receives—is a critical factor in influencing the development of the child's neural pathways that affect multiple functions, including language, intelligence, and behavior in later stages of life.

The benefits of preschool are sometimes dismissed based on standardized school test scores that characteristically weaken over time; however, growing evidence suggests preschool attendance remains influential into adulthood. Enduring benefits, particularly for those in disadvantaged families, include decreases in school dropout rates, criminal behavior, and drug use, as well as increased adult earnings. Preschool is also associated with outcomes identified as desirable in modern economies, including proficiencies in critical thinking, enhanced interpersonal skills, adaptability, and openness to differences and innovation.

In countries with ethnically and economically diverse populations, the positive benefits of high-quality preschool are seen in children from both low and middle socioeconomic classes, with stronger effects for children in lower socioeconomic circumstances, dual-language children, Aboriginal children, and children from immigrant families.

The persistence of deep poverty in rich countries and its prevalence in developing nations requires

evidence-based interventions. One important study from Jamaica shows the impact of nutrition and stimulation on children's early development. Children 9 to 24 months old whose height was two standard deviations less than the norm for their age and sex were randomly assigned to different groups. One group received dietary supplements; another, stimulation; and a third group, both stimulation and nutrition. The children were followed for 24 months. Stimulation alone and nutrition alone improved developmental outcomes, but the greatest impact came from combined stimulation and nutrition. The height of children who received both stimulation and nutrition increased to normal levels within 2 years. When assessed at ages 11 and 12, children who were stimulated showed improved IQ and cognitive function but were behind middle-class children whose growth was not stunted. Children receiving nutritional supplementation alone showed no cognitive gain.

A similar study in Colombia found that food supplements alone did not benefit the children but had substantial benefits when combined with stimulation.

The benefits derived from early education programs are directly linked to their quality. Researchers have related the quality of programs for young children to physiological measures, particularly to cortisol levels. Cortisol is a steroid hormone that is secreted during times of stress. Chronically elevated levels of cortisol affect all tissues in the body and are a risk factor for mental and physical health problems. Australian researchers found poor quality in child care centers associated with higher cortisol levels in children when measured at the beginning and end of the day. The most vulnerable children, those who began the day with higher cortisol levels, also had the most elevated end of day cortisol levels when in poor-quality programs.

Public Policy Influences on Early Education

A 2008 report by the Commission on Social Determinants of Health found that early education

programs are most effective when they are universally available, are part of a children's service network, include health and parenting supports, and are accompanied by adequate paid parental leave and income transfers.

The Organisation for Economic Co-operation and Development (OECD) Quality Network (2011) lists four factors required for effective early education programs:

1. The children regularly attend the programs. The effect size is greater when programs are available to all children rather than targeted to children in low-income families.
2. Early childhood education programs are adequately staffed.
3. Sufficient numbers of educators have a degree in early childhood education.
4. The teaching approach is child centered, with a high proportion of child-initiated activities.

The network does not set targets for staffing levels or educator qualifications, nor does it specifically define the curricula. Rather, it finds a correlation between these factors and outcomes for children. These are considerations for policy makers as they grow access to preschool programs.

Results from the Programme for International Student Assessment (PISA) support these findings. PISA is a triennial survey conducted by the OECD in cooperation with national education departments to assess the math, reading, and scientific knowledge of students nearing the end of secondary schooling. The 2009 reading assessment of students at age 15 shows that, in most countries, pupils who attended early education programs perform better than those who did not attend. Preschool attendees showed almost a full-year advantage in reading comprehension.

The PISA study discussed the role public policy can play. Longer attendance in early education programs, smaller child-to-staff ratios, and higher public expenditures per child during the preschool years all enhanced the reading scores of pupils at age 15. The largest differences are associated with

a higher portion of preschoolers attending early education programs and the number of years children attend. PISA found an average 10-point score increase for each year of preschool attendance by children ages 3 to 6 years.

The persuasive evidence of the widespread benefits of preschool education creates a strong rationale for an efficient, high-quality service system accessible to all children. Preschool's positive influence on educational outcomes makes it a compelling area for public investment. Education is the ultimate tool to address many economic and social challenges. It creates wider options for careers, raises employment levels, and lowers chronic unemployment, leading to higher standards of living, greater income equity, and a reduction in the social ills associated with poverty. A more educated workforce creates a more innovative and productive economy. These are the outcomes desired by progressive nations.

PRIMARY GRADE LEARNING SPACES

With the increased emphasis on children's achievement, there is also increased recognition about the need to design learning spaces that will result in greater learning. How this is conceived is embedded within the philosophical beliefs of the teacher and the school. This entry will look at historical and contemporary factors that affect philosophical beliefs, examine the foundation for establishing effective classroom environments, and consider learning centers as a way of designing classroom spaces for kindergarten through third-grade children.

Learning centers are self-contained areas with a variety of hands-on materials organized around a curriculum area or topic. For example, a math manipulative center in a kindergarten classroom might contain a variety of math games and activities aligned to state standards. These could include such things as different materials to classify, a variety of measurement tools such as balance scales and rulers with math challenge cards, games that involve counting, and two- and three-dimensional shapes with shape cards for composing shapes. Learning centers might also be

referred to as interest areas, learning stations, work stations, or activity areas.

Historical and Contemporary Factors

The philosophical belief of the teacher and school influence all areas of teaching and learning, including room design. Early childhood education has a rich history of encouraging active, inquiry-based learning based on the theories of Maria Montessori, Jean Piaget, and Lev Vygotsky. Constructivism, the belief that children actively construct knowledge based on experiences, background knowledge, and interests is at the heart of the early childhood belief. The teacher is viewed as a facilitator who sets up the environment and activities to stimulate child choice, initiative, experimentation, and social collaboration and who interacts with children in ways that deepen their thinking and learning. Constructivists believe that children are capable. Therefore, they trust the child-initiated learning process where children choose learning activities that are based on their developmental needs and interests. This would be balanced, however, with teacher-initiated learning.

The National Association for the Education of Young Children (NAEYC), the largest professional early childhood organization in the world, advocates for quality, research-backed practices for children birth to age 8. The NAEYC Developmentally Appropriate Practices Position Statement, based on constructivist beliefs, promotes integrated learning; a balance of child-initiated and teacher-initiated activities; firsthand, play-based learning experiences; and extended blocks of time for children to engage in a choice of learning activities.

However, many elementary schools do not follow constructivist philosophy, instead subscribing to the belief that the teacher is the primary transmitter of knowledge. The instructional strategies used are often whole-group instruction followed by individual practice. Classrooms are arranged with rows of desks facing the front of the room, limiting child conversation and focusing the attention on the teacher. In the late 1990s, it became more common to see tables and chairs for small

groups of children, or if there were desks, to see them arranged in clusters. For example, research on classroom arrangement revealed that while about a third of elementary classrooms in 1989 used a cluster model, 76% to 94% did by 2001. However, while teachers provided for more collaborative activities, there was still little child choice in many classrooms. Teachers continued to use primarily whole-group, teacher-initiated instruction with each subject taught separately. Learning centers, when used, were primarily folder activities allowing limited hands-on activity or deep engagement. Teachers often assigned children to groups and centers or used centers as a reward for completing seat work.

Today, several large initiatives are supporting a more collaborative, project-based instructional model consistent with constructivism. These include the Partnership for 21st Century Skills and the ASCD (Association for Supervision and Curriculum Development) Whole Child Initiative. Nineteen states are the leaders in implementing the 21st Century Goals. The goals stress the need for children to learn to think and work creatively with others; implement innovations; effectively communicate and collaborate; engage in critical thinking and problem solving; master core subjects; and gain information, media, and technology skills. In schools subscribing to this philosophy, an observer is likely to see learner-centered curriculum based on student needs and interests, curriculum where subjects are integrated rather than taught separately, project-based learning, collaborative groups, and space divided into learning zones.

ASCD's Whole Child Initiative is endorsed by more than 70 national organizations and several international groups. The focus is on providing environments and curriculum to support healthy children who are physically and emotionally safe, engaged in personalized learning, connected to the school and community, supported by responsive adults, and challenged and prepared for success. The approach stresses learning that is personalized, active, experiential, cooperative, and project based.

The Foundation

At the same time that national movements have been emphasizing constructivist approaches, there has also been an increased emphasis on ways that schools can improve test scores. As might be expected, child on-task behavior and engagement is linked to learning and better achievement test results. Both the learning and room design are linked to on-task behavior. In a recent large-scale study, elementary students included in the research were found to be off-task about 30% of the time. Previous studies show a range of 10% to 30% off-task behavior. Children were more on task when working in small groups, rather than when working in large groups at desks or when working individually. Children were also more on task when seated at the carpet than when at desks.

Many studies have also linked achievement test scores with school and classroom facilities, including air quality, noise level, lighting, temperature, and density or crowding. Significant links have been found between these variables and children's achievement, rate of illness, and attendance. Teacher retention and satisfaction is also related to these variables. Through classroom interventions, teachers can assist in ameliorating some of these. For example, since indoor air quality in schools has typically been found to be up to 100 times worse than outdoor air quality, teachers might open windows when possible.

Teachers can also influence density levels. High density levels negatively affect children's cortisol levels, social interactions, attention span, and achievement. Crowding is especially detrimental for children who have special needs or who experience crowded environments at home. Reducing density, and ensuring that there is enough open space for children to freely move and work, can improve test scores. Teachers can free space by decluttering, removing any items not currently in use, considering whether there is a need for a teacher's desk, and replacing horizontal bookcases with high bookcases where the top portion is used for teacher storage. Because most elementary classrooms are

smaller than the recommended 50 square feet per child, it is necessary to ensure that spaces are multipurpose. For example, the group gathering space might be used for movement and music during learning center time.

Ensuring children's physical needs are met can also increase achievement test scores. This includes providing for children's comfort through having soft areas, a variety of types of seating, different lighting options, the ability to move, and different degrees of privacy. Additionally, having readily available drinking water, snacks, and bathrooms in the classroom can add to children's comfort level.

Arranging Spaces for Student Engagement

To be effective, the room design needs to be consistent with the teacher and the school's philosophy of education and provide for child engagement and on-task learning. Teachers who support the constructivist philosophy, the Whole Child Initiative, and the Goals of the 21st Century would provide different types of spaces including a space for the whole group to gather. This space would contain needed technology equipment and be large enough for all children to easily see and be able to move around. There would be many areas to accommodate small groups and spaces for independent work such as carrels with headphones. Research with preschool children shows the value of having retreat areas. These encapsulated spaces allow children to escape the busyness of the classroom to calm down or engage in quiet contemplation or deep thought. They are especially important for children with sensory or attentional issues. When retreat areas are available, children interact more with peers, engage in less wandering behavior, are less aggressive, and display enhanced cognitive development.

Learning centers also assist in supporting the constructivist philosophy, the Whole Child Initiative, and the Goals of the 21st Century. While using learning centers, children engage in active inquiry and experiential learning. Choice, autonomy, self-regulation, and responsibility are vital

parts of the learning center model, with children having a choice of what centers to engage in, what materials to use, and whether to work alone or with others.

When the centers are well developed, children choose centers and materials that match their interests and development. Studies show that when children have choices of activities, they are more self-directed, have less disruptive behavior, and are more engaged in tasks. While children are typically given free choice, there may be required activities that children need to accomplish each day or each week.

When teachers view centers as a valuable learning opportunity, they dedicate enough time so that children can engage in in-depth work. Many experts recommend that this be at least an hour. Rather than being a reward for completing all seatwork, the centers are often used in place of a more traditional approach of learning that emphasizes completing paper-and-pencil tasks. The teacher is actively engaged in supporting children's learning as they use the centers. This includes observing, scaffolding learning, supporting peer interactions, acknowledging children, and assessing and documenting learning. When scaffolding learning, teachers might ask open-ended questions, provide additional information and materials, model new vocabulary, discuss concepts, or be a play partner.

Typical learning centers in the elementary classroom, include literacy (reading, writing, listening), social studies and project work, math manipulative, dramatic play, creative art and music studios, science lab, and an engineering and construction center. While each center is designed with a unique focus, as children use the center they are engaged in integrated learning. For example, children using a science center focused on density and buoyancy might be reading task cards, recording their predictions and their findings as they experiment with items that sink and float, and looking at books about buoyancy. Technology is infused throughout the centers. For example, a QR code might be placed in the music lab. When a child scans the code with a tablet,

he would see and hear a musician demonstrating ways to use a new instrument in the center. Another QR code might bring children to an Internet site that lets them compose their own music, choose an instrument to play the music, and hear the music played back. In addition, literacy and math are typically infused in every center. For example, the dramatic play grocery store might contain a cash register, play money, a scale, order sheets, and receipt books.

To be effective, learning centers should be changed and enriched to assist children to engage in deep learning. Whether establishing or changing the center, the teacher considers children's development, their interests, their culture, and the relevant learning standards. Effective teachers not only ensure that the materials represent the diversity within the group; they also expose children to additional forms of diversity. For example, the music area would contain a variety of types of music supplied by the children's families as well as different types of cultural music.

Learning centers often look different depending upon the grade level. For example, a kindergarten classroom might have a home living center for dramatic play while a second-grade classroom might have costumes and a stage. While large unit blocks with accessories might be found in a kindergarten engineering and construction area, LEGO robotics might be located in a third-grade engineering and construction area.

To reduce distractions and increase time on task, well-designed environments have boundaries between centers. These are created with such things as furniture, shelving, and portable low screens or by hanging sheer material from the ceiling. Research reveals that children are more deeply engaged in their activities and are less distracted when there are well-defined boundaries. In addition, they display more appropriate behavior, positive interactions, and cooperation resulting in teachers who are less controlling and more engaged in learning activities. Separating quiet (library) and active centers (construction) also enhances child engagement.

High-quality learning centers are stocked with an abundance of accessible hands-on learning materials and authentic, quality tools that provide for a variety of interests and developmental levels. The materials are well organized so that children can see their options and easily locate and return materials to the proper place. To assist in keeping children on task, all needed materials are located within each center. This might mean that some tools and materials are located in multiple centers. For example, colored pencils might be found in the art center, writing center, and science center. Materials are designed to be meaningful and interesting to the children.

Several early childhood theorists and approaches discuss the need to provide aesthetic and natural materials that provide a range of affordances or opportunities for learning. Materials are also more enticing and interesting when they are displayed aesthetically. For example, children can practice classification using a variety of different items including natural items such as pine cones, leaves, or seed pods. When choosing the items to classify, the teacher needs to consider the group and also the opportunities for the affordances that they provide. When children sort seed pods, they also have the opportunity to learn more about the trees and bushes in their local area. Their observation skills increase as they see the differences that exist among the same type of pod. Rather than the plastic sorting trays found in many programs, theorists such as Maria Montessori and Loris Malaguzzi (the inspiration behind the Reggio Emilia-inspired approach) would recommend using beautiful glass, wooden, or metal sorting trays. Using beautiful materials shows respect for children, adds to the aesthetics of the room, and often results in children treating the materials with greater care.

Affordances also need to be considered for each activity added to a center with teachers asking themselves what additional materials will increase children's learning opportunities. For example, adding journals, writing materials, and magnifying glasses can increase the affordances of a butterfly garden.

Teachers also need to carefully consider what is on the walls. What is displayed provides an immediate message about what and who is important. Wall space can effectively be used to display children's ongoing and completed work; photos of children, teachers, and families; and informational and inspirational posters. However, when walls become too crowded with materials they become distracting and ineffective. For example, a study examining kindergartners engaged in a science activity found that they were more attentive and learned more when the room was less distracting. Colorful borders and catalog-purchased cutouts, a hallmark in many primary classrooms, can add to the visual stimulation. Instead, the walls should be personalized for the learners. One way teachers do this while still limiting visual bombardment is to use child-created materials and posters. For example, rather than commercially purchased ABC cards, children might create an alphabet by taking photos of environmental print or of natural items shaped like an alphabet letter.

When planning wall displays, teachers need to carefully consider the purpose and the size of the display as a way to reduce visual clutter. Likewise, most design experts recommend avoiding brightly colored rugs, storage containers, and shelving and instead using more neutral and natural colors.

Individualized storage for children's and adult's possessions, work, and treasures is needed. Storage to replenish and rotate materials is also important. However, classroom storage should be saved for items that are frequently used. If possible, storage for infrequently used items and items purchased in bulk should be stored outside the classroom. To reduce visual stimulation, adult storage can be enclosed with doors, curtains, or bamboo roll-up shades. Storage is also needed to support ongoing project work, a place to showcase and to store two-dimensional and three-dimensional works in progress.

Effective teachers using the learning center model also consider how the entire room provides a welcoming and engaging atmosphere. Lighting, flooring, shelving, and displays all contribute to

the ambiance. A welcoming, effective room is clutter free, aesthetic, personalized, and filled with interesting, challenging, and engaging materials.

PRIMARY GRADES

The field of early childhood education formally embraces programs and practices for children from birth through age 8, or third grade. Research-based knowledge about how young children develop and learn makes a convincing case for capturing the early elementary grades within the birth through age 8 programming continuum. As Jack P. Shonkoff and Deborah A. Phillips have observed in their research on child development, the ages of 6 through 8 years are a critical period for children's brain development. As is true for younger children, primary-grade children's development and learning are inextricably interrelated across multiple domains. Indeed, there is a growing body of research to support the conclusion that progressions of learning and development that begin in children's earliest years extend through the primary grades. It is important for primary educators to be intentionally responsive to these developmental perspectives on children's learning if they are to provide optimal experiences that pave the foundation for children's ongoing educational success and well-being. Still, this vision of a cohesive early childhood programming continuum that actively incorporates the primary grades has yet to be fulfilled in reality. This entry examines why kindergarten and the primary grades have frequently been excluded from the theory and practice of early childhood education. It further examines why early childhood educators

and researchers are increasingly turning their attention to children from birth through third grade. The final section of this entry outlines key practice areas for primary educators.

The Status of the Primary Grades in Early Childhood Education

In practice, early childhood education has focused most fully on the birth to 5-year age range, emphasizing developmentally based approaches for serving infants, toddlers, and preschool children. Kindergarten, historically conceived as a child-centered bridge into elementary school, has been increasingly shaped by primary-grade practices and has reportedly become "the new first grade" with more time on academics and less time on play, exploration, and socialization, as is also the case across all the primary grades. In addition, the primary grades typically function as separate grade-level units with little consideration for the flexibility and continuity of learning experiences that are required to fit the developmental patterns of young children as they transition from one year of early elementary school to the next.

Gaps in fully embracing kindergarten and the primary grades as the critical upper end of the birth-through-age-8 early childhood continuum reflect complex differences in traditional program settings, funding streams, governance systems, grade-level structures, and accountability pressures of early care and education services for young children of varying ages. At a deeper level, in early childhood education, birth to age 5 and kindergarten to third grade reflect differing professional cultures that include contrasting expectations for children, terminology, approaches to teaching and learning, and relationships with families. Primary-grade educators' strength is typically rooted in content-area teaching. By contrast, early childhood educators who focus primarily on children from birth to age 5 tend to demonstrate greater understanding and support for children's social and emotional development, including their approaches to learning. Both groups have much to learn from each other's strengths. Both groups likewise share

challenges that must be collectively addressed if we are to actualize the vision of continuity and quality across children's early education experiences from birth through the primary grades.

Renewed Focus on Primary Grades as Early Childhood Education

Professional consideration of the primary grades has shifted as views of early childhood education have become more comprehensive and inclusive of the full continuum from birth through third grade. New frameworks for birth through third grade, often referred to as P-3 or PreK-3rd, are focusing attention on the critical importance of the primary grades, guiding educators and policy makers to shape renewed primary grade approaches and practice guidelines. These frameworks share many elements in common. Notable among these are calls for greater alignment of children's learning experiences from pre-K (or younger) through the primary grades; balance among child-initiated and teacher-guided instructional approaches; a more holistic focus on cognitive, academic, and social-emotional learning; well-rounded enriched curricula; and collaborative family engagement.

As efforts to align and transform young children's learning opportunities across birth through age 8, and particularly across preschool through the primary grades, PreK-3rd initiatives have been spurred by contemporary challenges. Greater numbers of young children attend school as prekindergarten programs expand, and the linguistic and cultural diversity of the young children who are enrolling continues to increase. The most influential challenges, however, are the unabated disparities in learning outcomes for low-income, African American, and Latino children. Not only do these disparities show up very early in children's lives; they often widen as vulnerable children progress through the primary grades. According to research by the Institute of Educational Studies, for example, by the fourth grade only about one-fifth of African American and Latino children and less than one-half of White children read at or above grade level. These data place a spotlight on the

primary grades for the important role they must assume in preventing and reducing opportunity and achievement gaps. As Lisa Guernsey and Laura Bornfreund (2015) observe, "early childhood education doesn't end with pre-K" (n.p.).

The promising news is that research and practice innovations highlight the opportunities that focused attention to the primary grades support children's developmental and educational success. For example, Arthur Reynolds's rigorous, longitudinal research on the Chicago Child-Parent Centers, a preschool through third grade program for children at high risk, has shown greater long-term impact for children who participated through third grade as compared with children participating in preschool only. These impacts included substantially improved achievement of on-time high school graduation. Case studies from notable public school district efforts, such as Montgomery County, Maryland, and Union City, New Jersey, likewise demonstrate the impact of including the primary grades in systematic efforts to employ early childhood education as a foundation for transformative school reform. In these and other exemplars, researchers and district leaders cite the continuity of learning from preschool through third grade, consistent and challenging curricula across the primary grades, and sustained family engagement as key levers for effectiveness.

What Matters Most for Primary Grade Instruction

As the primary grades are folded into considerations of early childhood education to be regarded as an investment in children's optimal development and learning, researchers and program leaders are asking the same question: What matters most for high-quality, effective early education practices, particularly for children placed at risk? In general, the conclusions for the primary grades are similar to those that emerge when the lens is placed more narrowly on preschool education. There is no unitary instructional approach that marks an effective primary classroom. Rather, diverse instructional approaches such as guided

instruction; direct teaching; child-initiated inquiry; or play and diverse formats such as whole-group, small-group, or independent learning serve children best when they are used in intentional, balanced combinations. The key is that all instructional approaches are constructed based on a child developmental perspective.

Beyond balance, a research-based practice imperative that also remains constant regardless of instructional approach is the presence of warm, responsive teacher–child relationships and stimulating two-way interactions. Indeed, strong, emotionally supportive teacher–child relationships coupled with extended learning-focused interactions are necessary to promote active engagement and high levels of learning for all children in the primary grades. Not surprisingly, these interpersonal elements of practice demonstrate even more compelling evidence for their gap-closing importance and for serving a critical function in the engagement and educational success of low-income children and children of color during their early years of schooling. Placing a priority on interpersonal relationships and interactions as central channels for teaching and learning may require a mind-set shift among many primary teachers given their prior experience and preparation.

The science of child development and early learning also points to additional high-impact elements that characterize effective primary grade practices when applied within the context of balanced instruction and supportive teacher–child relationships. These research-based elements that span variations in specific instructional approaches and content area emphases include four key practice commitments:

1. *High-Quality Language Environments.* In effective primary classroom environments, oral language and deep vocabulary development are promoted as foundations for conceptual knowledge and reading comprehension. Interactive conversations and extended discourse with teachers and peers are the norm, with children having abundant opportunities to engage in purposeful talk throughout daily routines and learning experiences.
2. *Focus on the Whole Child.* First and foremost, a whole child focus means that explicit strategies to support children’s social and emotional competence are embedded within primary grade practices and instruction. Teachers scaffold children’s emerging development of self-regulation and productive peer relationships. Similarly, children’s emotional and behavioral challenges are interpreted as expressions of what children need and as opportunities to provide instruction and support in reducing children’s stress.
3. *Intellectual Rigor.* In high-quality primary classrooms, the curricula in use evidence rich content that is balanced across subject-matter areas, and take into account developmentally informed learning sequences. Children are taught skills and basic content knowledge, but are also intentionally engaged in higher order thinking, problem solving, and inquiry that is facilitated through teacher–child interactions and scaffolding. Children are given opportunities to be not only question answerers, but also question askers. Rather than just learn about math, science, social studies, art, and other subject areas, they become mathematicians, scientists, sociologists, and artists.
4. *Cultural and Linguistic Responsiveness.* Relationships, knowledge of early childhood development, and understandings of content that go beyond the standards are obviously core ingredients of effective primary grade instruction. Primary grade classrooms that magnify the power of school-based learning to reach each and every child, however, also value children’s home culture, language, and background knowledge as resources. Teachers in these classrooms actively seek out insights into children’s and families’ funds of knowledge and use these insights to build inclusive classroom learning communities.

Renewed attention to the primary grades poises early childhood education to make a significant impact in reducing and eliminating opportunity and achievement gaps that persist beyond preschool. More than this, a commitment

to high-quality practices in the primary grades that build upon the early childhood learning continuum can bring new levels of excellence and inspiration to the education of all children. The realization of this vision is within reach as early childhood educators and researchers look across professional divides to apply the best of what is known about young children's learning and development, content, and instructional practices.

PRINCIPALS, ROLE OF

Principals come to their leadership roles with a wide variety of backgrounds. These individuals have received graduate degrees that enable them to assume the role of principal. Some individuals may have had preparation as PreK–3 teachers; however, others may have had preparation to teach older elementary students, middle school students, or even high school students.

The path to the role of principal varies from setting to setting. Rural settings may have very different administrative configurations than urban settings have. The number of students enrolled in a rural district often dictates the number of administrators in a district as well as the individual who will be responsible for the early childhood program.

A review of the states' department of education websites provides an example of differences that exist from state to state. An examination of administrative certification practices in the 50 states in 2014 revealed many differences in the availability and specificity of administrative certificates. According to individual websites for each of the 50 states, 16 states had administrative certification available for Grades K–12 and eight states had administrative certification available for Grades PreK–12. Some states did not indicate grade levels for administrative certification or did not indicate a listing for any administrative certification at all.

The Interstate School Leaders Licensure Consortium (ISLLC) Standards for School Leaders specify the knowledge and skills necessary for district and school leaders to build teams of teachers and leaders that improve student learning. The standards were first developed in 1996 and revised in 2008 before another revision on them began in 2014. The ISLLC standards are a project of the Council of Chief State School Officers (CCSSO) in partnership with the National Policy Board for Educational Administration (NPBEA). CCSSO and NPBEA, with support from the Wallace Foundation, engaged in the 2014 ISLLC Leadership Standards Refresh Project. As of May 2015, they were seeking additional public comment on the revised draft standards.

The primary goal of the standards is to articulate what effective leadership looks like in the public education system. The standards are designed to be used by all education leaders.

In the draft format, the standards include vision and mission, instructional capacity, instruction, curriculum and assessment, community of care for students, professional culture for teachers and staff, communities of engagement for families, operations and management, ethical principles

and professional norms, equity and cultural responsiveness, and continuous school improvement. Each of these standards pertains to the role of a principal who has responsibility for early childhood education.

For instance, the principal needs to be able to articulate the vision and mission of early childhood education. The principal must be able to promote the academic, social, and fiscal benefits of early childhood education to all of the school's stakeholders. The principal needs to "know the facts"—the educational and economic benefits of an early investment in early childhood education. The principal needs to be able to report the indicators of the impacts early childhood education has had in student achievement.

The principal is responsible for achieving high-quality programs in the school. The quality indicators for early childhood education should be evident in the school. The principal must enhance instructional capacity by recruiting and hiring teachers and staff who have specific training in child development, early childhood education, and expertise in subject matter such as literacy, math, science, social studies, physical education, and the arts. Professional development opportunities must be tailored to meet the needs of the teachers and staff members. A principal who has the opportunity to hire teachers for early childhood positions should seek individuals who have specific preparation in child development and teaching children in PreK–3 settings.

A principal should emphasize child development and learning by providing continuing education opportunities for teachers and staff members. School-sponsored events focused on child development and learning may be helpful to families. As a spokesperson for early childhood education, the principal can use speaking opportunities to inform the community of the importance of child development and learning.

In the early childhood setting, group sizes are small and adult-child ratios should maximize individualized learning opportunities and experiences for the children. The learning environment is well organized, safe, and healthy, and designed to

accommodate the ways young children learn. Families' involvement in their children's education is emphasized.

The principal should involve early childhood teachers, as well as teachers of other grades, in school conversations, planning, and decision making. The principal demonstrates administrative support of the early childhood program by regular visits to classrooms, observations of classrooms, feedback to teachers and staff members based on the visits, and regular evaluations of teaching. The principal's presence in the teaching and learning environment is an endorsement of early childhood education.

Teacher turnover is a persistent issue and a principal's concern. The principal's task is to create a satisfying teaching environment. Teachers must be recognized for their contributions and successes. The principal should encourage teacher growth and development opportunities. Working conditions must be examined in order to reduce frustration with issues such as teacher isolation, working conditions, or the structure of the school day. The environment should be designed as the best teaching and learning setting possible for students and the teachers.

The principal needs to be knowledgeable about developmentally appropriate practice (DAP) when talking with teachers and staff as well as when making decisions about programs. The principal can provide opportunities for teachers to meet and discuss age appropriateness, individual appropriateness, and social and cultural appropriateness. The principal should observe evidence of DAP in classrooms and discuss the teachers' DAP-related knowledge and skills.

The principal needs to know how young children develop. Attendance at professional meetings that focus on early childhood development and early childhood education is essential for the principal who is responsible for leading early childhood programs. Reading professional journals that focus on early childhood is another approach to acquiring greater knowledge of the topic. Publications by the National Association for the Education of Young Children (NAEYC) such as

Young Children are useful sources for professional development. The National Association of Elementary School Principals (NAESP) 2014 publication *Leading PreK–3 Learning Communities: Competencies for Effective Principal Practice* is essential reading for the principal who leads an early childhood program.

Observation of young children in classrooms and outdoors increases the principal's experience, knowledge, and insight into the development of young children. Time spent observing the teaching practices of experienced early childhood specialists helps the principal gain a greater understanding of the skills and strategies used to enhance learning in the early childhood setting.

Family involvement is critical to the success of early childhood education. The principal's role is to design an environment that is welcoming to all of the family members in a young child's life. The principal must anticipate the feelings of family members about coming to school and consider the past experiences the adults may have had in school settings. Parents need to experience value in coming to their child's school. With this in mind, the school should provide opportunities for family involvement and serve as a source of information about how families can become involved in their child's learning experiences. Information about community resources for families should be available as well. Teachers and staff should be reminded of their primary importance to the families since it is these professionals who have the greatest amount of personal contact with the young children.

PROFESSIONAL DEVELOPMENT FOR DIVERSITY

As the United States' population becomes more diversified and heterogeneous, there has been increased professional awareness about the importance of understanding diversity in education. Specifically, there has been an increased recognition of the need for educators with cross-cultural competence and the ability to address the needs of children from diverse backgrounds. Research and policy inform us that policy makers, personnel in higher education institutions, and school and early care and education program staff must take professional development in diversity very seriously. However, meaningful, effective training and ongoing professional development in diversity continue to be lacking. This entry examines the impact of changing demographics in U.S. classrooms and some of the challenges faced by educators, administrators, and policy makers as a result. This entry further discusses the need to intentionally and systematically integrate cultural, linguistic, socioeconomic, and ability diversity (CLAD) in teacher education programs and in-service professional development as a means to support quality educational experiences for diverse student populations in order to reduce the achievement gap. Additionally, some promising and innovative preservice and professional development programs in diversity are presented.

The Changing U.S. Demographic: Implications for the U.S. Educational System

The United States' demographic trend has been undergoing substantially rapid cultural, racial, linguistic, socioeconomic, religious, and generational change due to fertility patterns, migration, and immigration. In many U.S. counties today, over 50% of the population is made up of linguistically, culturally, and socioeconomically diverse families. The U.S. Census Bureau has projected that by 2050, non-Hispanic Whites will make up less than half of the population, while the Hispanic and Asian populations will more than double and combined will make up about a third of the population. Demographic trends predict that the United States will be a country with a highly diverse population. The changing demographic trend has implications for the early care and education system, its policies, and classroom practices.

As the general population diversifies, so do American classrooms. The National Center for Education Statistics has projected that public school enrollment in prekindergarten through Grade 8 will increase to 37.6 million students in 2024–2025, up 7% from the 35 million enrolled in 2012–2013. A similar trend is also evident in early learning programs as more mothers are employed outside of the home. In their *Child Care in America 2012 State Fact Sheets*, Child Care Aware of America reports that 11 million children under age 5 were in some type of child care arrangements. This number continues to increase exponentially each year for young children from multicultural backgrounds. One stark implication of the U.S. demographic change is the wide and deepening achievement gaps between White and minority students and the low graduation rates for CLAD students compared with White students. With rapidly increasing numbers of diverse children in early care and education programs, state policy makers, program leaders, and higher education institutions must ensure that teachers and teacher educators are well grounded in understanding diversity and in meeting the needs of all children.

Barriers to Professional Development for Diversity

Training in diversity has become more critical for early childhood education professionals because American families have become increasingly diverse and complex recently. One out of five children in the United States lives with at least one parent who was born in a country other than the United States. An increasing number of children in early learning programs and school systems are recent immigrants, most of whom are English language learners. Many teachers believe that they lack competencies to best meet the learning needs of all children and to authentically partner with their families. Early educators need knowledge, skills, competencies, and dispositions to work effectively with diverse students and their families.

There is compelling evidence that teacher professional development for understanding diverse children and families not only benefits teachers but also improves program quality and child outcomes and has the potential to close the achievement gap. Unfortunately, national and local barriers (institutionally and interpersonally) exist in the pursuit of professional development in diversity. These barriers include persistent lack of public understanding that professional development on diversity does make a difference. The lack of state policies regarding understanding of diverse children and families, inadequate professional development content and delivery methods, and lack of awareness of or access to professional development in diversity continue to exist. There is uneven attention to diversity content in higher education teacher preparation programs with some professional preparation programs strongly emphasizing social justice issues and others providing only a superficial introduction to an anti-bias approach. Financially strapped programs complain of lack of funding for professional development, and early learning professionals, juggling work-life balance, indicate that they have precious little time for ongoing professional development. As a result, continuing education is often disregarded. To ensure that early educators are best able to meet

the needs of all learners, it is necessary to look at ways that these barriers might be eliminated and more meaningful diversity content and effective delivery methods be put into place.

Inadequate Formal Training and Professional Development on Diversity

Since the 1990s, diversity and cultural competency have evolved from being buzz expressions to something of critical importance in education. Early educators acknowledge that dealing with diversity is a major challenge today. They also admit that all preservice and professional development programs must equip teachers with the skills and competencies to effectively work with all children. As noted by Linda Darling-Hammond and Silvia Paloma Garcia-Lopez (2002),

To teach effectively, teachers need to understand how learning depends on their ability to draw connections to what learners already know, to support students' motivation and willingness to risk trying and to engender a climate of trust between and among adults and students. (p. 9)

However, many teachers believe that they are not well prepared to teach children who are from cultural and linguistic and socioeconomic backgrounds different from their own. While many states and preservice programs have made some progress in addressing diversity in program standards and curriculum, intentional integration of cultural, linguistic, socioeconomic, and ability diversity into educational pedagogy and professional development for teachers and meaningful field experiences are inadequate.

A study by the Center for Research on Education, Diversity and Excellence (CREDE), which took place from 1996 to 2011, reveals that integration of diversity into preservice and in-service programs is quite minimal. Among other things, the report recommends the complete infusion of cultural, linguistic, socioeconomic, and ability diversity into programs. A 2006 study of 662 teacher training programs by Aisha Ray and Barbara Bowman also confirmed CREDE's conclusion that minimal

attention was given by teacher education programs to diversity content. The study revealed few hours of coursework, no specific strategies, and little practice time given to teaching preservice students how to effectively work with diverse students and families, hence providing an explanation about why teachers feel unprepared to support the learning of diverse children even after taking relevant college courses or professional development. Aisha Ray, Barbara Bowman, and Jean Robbins, in the executive summary of the study of 226 colleges and universities, report that of the 226 preservice programs examined, “only 7 percent of Bachelor Degree programs indicate that they expect future teachers to have an experience in which they will be exposed to diverse children” (p. 1). Many trainings lack specific strategies in working with diverse children and families and experiential learning opportunities in diverse communities.

Promising Strategies for Diversity Training and Professional Development

Rapidly changing American demographics continue to pose significant challenges to early learning systems to equip teachers with CLAD competencies and skills to work in the ever expanding cultural context of U.S. classrooms. There must be an understanding of how culture, language, and ability differences influence the way that children view and interact with their world, and how children behave and learn. CLAD principles and competencies must be systemically infused into core curricular content and pedagogy at all levels of educator professional preparation as well as in institutional and organizational practices. In her capacity as higher education manager at the Pennsylvania Key, having recognized the need of incorporating diversity training as an integral part of preservice education, Bernadine Ahonkhai recommended the provision of high-level professional development on diversity for education faculty and instructors. Under her leadership, from 2008 through 2011 the Pennsylvania Office of Child Development and Early Learning

(OCDEL), in collaboration with the Pennsylvania Key, launched the Pennsylvania Higher Education Institute on Diversity. The institute provided evidence-based models, strategies, and best practices for diversity-infused preservice teacher education programs and professional development offerings. Such promising professional development initiatives have the potential to yield transformative effects on teacher educators in increasingly diverse educational settings and prepare teachers to be more effective in their work with all children and families, regardless of their backgrounds.

A 2008 survey of teachers by Earl Thomas and David Lamont Bell revealed that diversity training implemented in a nonthreatening, nonjudgmental environment with supportive opportunities for teacher reflection and practice has the potential to foster a change of attitude and practice among teachers and teacher educators. Professional development is more effective when it is presented not as a single event, but as an ongoing learning opportunity to acquire knowledge, competencies, and dispositions to improve one’s ability to effectively foster children’s development and learning and also to grow as a professional in an ever changing early education environment. Being an effective professional in today’s diverse early childhood programs requires learning new patterns of behavior and successfully applying the skills in cross-cultural interactions with diverse students and their families. Educational leaders and policy decision makers should emphasize the critical importance of ongoing participation in professional development on diversity by teacher educators and teachers in order to achieve this dual goal.

The Teaching Case Method, Simulation Model, and Role Play

Teachers play the most critical role in the education of young children. They have a significant impact on children’s learning, development, and academic success. Research has revealed some barriers in the pursuit of professional development on diversity. Foremost among the barriers is the lack of structured, focused diversity teaching strategies and

inadequate robust diversity content. Recently, some innovative and promising professional development strategies on diversity for teachers and teacher educators have been developed. Harvard Family Research Project's (HFRP) use of race, ethnicity, culture, and class as the context for its teaching case model on diversity has proven to be a powerful training method, beneficial to both students and instructors. Teaching cases present opportunities with a menu of different activities beyond the case discussions. The use of "live cases" similar to a guest speaker or someone from the local community who can speak firsthand on diversity issues provides a rich platform for professional development in cultural, linguistic, socioeconomic, and ability diversity issues.

The teaching case scenarios are structured around various cultural and ethnic groups with stories that offer real-life experiences to participants. The teaching case model can generate lively discussions as participants critically rethink their assumptions about those who are from different cultural backgrounds than their own. Students explore their individual identity, consider multiple perspectives, and continuously self-reflect and evaluate their cultural biases and assumptions. The teaching case model has the ability to foster teachers' attitudinal and classroom practice changes, improve the overall school climate, and enhance students' academic performance. Research-based teaching cases help educators connect theory and research to classroom practice by reflecting critical issues in family-school relations, especially with culturally diverse families and those who live in poverty. The cases provide learning experiences that will help educators communicate, build relationships with diverse families, and facilitate learning in CLAD classrooms effectively, equitably, and nonjudgmentally.

Teaching case methods should, however, be combined with enriched classroom activities, discussions, and simulations in which students and families engage in face-to-face interactions or online with virtual families in a safe, nonjudgmental, noncritical space. Such simulation models (e.g., Head Start simulation model) allow teachers to practice interaction with families and encourage active listening, mutual

sharing of information, and respectful relationship building. Simulation models can be used individually or as a group with opportunities for reflection. Role playing is another strategy that has been found to be quite effective in teaching how to work with CLAD students and families. The use of role playing, like simulations, to practice interactions with families should also be conducted in a safe, nonjudgmental environment. Virtual families and members of the local community who experience diversity-related issues (a teacher, principal, or other community members) can be incorporated in the "live cases" for the teaching-learning experience to be meaningful and beneficial.

Diversity Resources and Supports for Teachers and Teacher Educators

Challenges relating to diverse children and families in U.S. classrooms have been acknowledged by educators as one of the most pressing issues in early childhood education today. Supporting teachers in their efforts to provide thriving environments for all children and students to learn and develop to their full potential requires a multifaceted approach. Educators who are engaged in meaningful, ongoing conversations about teaching and learning and the impact of children's cultural, linguistic, socioeconomic, and ability backgrounds on their behaviors, development, and learning will find greater success than those who pay little attention to CLAD differences. To help educators sustain the competencies acquired in their learning environments, including the use of current resources on diversity, continuous support and feedback from supervisors or administrators should be provided to educators on an ongoing basis. Such practice can foster a strong sense of confidence in educators, thus supporting them to become increasingly effective in their work with all children and families. Growth in diverse student populations in U.S. classrooms demands that teacher educators, teachers, and caregivers become CLAD competent in facilitation of learning in multicultural environments. Preservice education should systematically integrate CLAD content into the curriculum and pedagogy and include meaningful field-based

experience in diverse classrooms. Diversity training and professional development should not be a one-shot deal with limited or no follow-up opportunity. It should be offered on a continuous basis in order to foster a powerful school culture and climate, and promote a learning community whereby educators can share information and bounce ideas and problems off each other. Professional development in understanding diversity helps to expand educators' understanding of diverse student populations, social justice issues, and intentionally responsive teaching in increasingly CLAD settings. A well-focused and high-quality diversity professional development program based on innovative and promising models, such as the Pennsylvania Higher Education Institute on Diversity, the teaching case model with real-life issues and experiences, simulation models, or role playing, and active, open-minded participants, can lead to changes in educator attitudes and classroom practices.

PROFESSIONAL DISPOSITIONS OF EARLY CHILDHOOD EDUCATORS

Professional dispositions are the tendencies to think and act in certain ways that are valued by the field. Professional dispositions go beyond knowledge and skills; they are not just beliefs and they are not just actions. Professional dispositions are vital because they become a way of being for a professional that affects the why, how, and what one does as an educator. Dispositions have also been referred to as habits of mind. This entry first provides a more detailed examination of professional dispositions with an example that illustrates how building dispositions is an interactive and ongoing process. Next, it examines ways to develop professional dispositions. It concludes with a look at the benefits of such development.

For early childhood educators, professional dispositions are the thinking and doing that inform or drive their practice of teaching, caring, and leading. Professional dispositions for educators may include cognitive processes such as exploring, examining, analyzing, reflecting, and documenting different teaching and learning aspects. These dispositional processes may also include the intentional bumping into an event or belief that provokes a need to resolve one's own disequilibrium about a learning event. Over time, these processes lead to professional dispositions in which the educator is responsive and intentional, as well as an advocate for each and every child.

When moving beyond one's own educational setting, whether it is the classroom or a childcare facility, professional dispositions also may involve the careful observations of one's colleagues and providing interactive feedback, supporting and involving families, being involved in the field, and continuing to grow and develop as a professional. Basically, professional dispositions move from personal to professional, first in one's local setting and then to wider leadership settings.

Professional Dispositions Influences

Professional dispositions interact with and are shaped by context, practices, documented evidence, beliefs, theories, and time (see Table 1). As a result, they are highly personalized and contextualized. An example derived from observations and conversations across different settings is provided below to help illustrate this; pseudonyms are used to preserve confidentiality.

Professional Dispositions Example

Ms. Lucia is standing in the mulch surrounding the picnic table, observing Sloan (3.5 years of age). Sloan has climbed onto the picnic bench and is standing up. She steadies herself with her hand on the tabletop. Eventually, Sloan climbs onto the top of the table and stands with her arms extended for balance. While not saying a word, Sloan has a huge smile on her face. Ms. Arya (who is Ms. Lucia's coteacher) walks over at this point and asks why she hasn't told Sloan to get down because it "isn't safe." Ms. Lucia just replies, "It's okay. I'm right here with her." Ms. Arya walks away visibly upset.

As soon as the children are settled down for their naps, Ms. Lucia joins her coteacher for planning time. While she is walking to the resource room, she wonders if she should bring up the incident with Sloan or if Ms. Arya will. Ms. Lucia doesn't have to wonder for long because the first question Ms. Arya asks is "Why were you letting Sloan break the playground rule? We don't climb on the picnic table." The following discussion ensues:

Ms. Lucia: Sloan tends to be particularly timid regarding more physical activities. Today, she was taking a real risk climbing on the table. I wanted to support her risk taking through careful observation and close proximity rather than redirecting her to someplace safe, which is Sloan's usual mode of operation.

Table 1 Professional Dispositions

<i>Professional Dispositions Related to Teaching and Learning</i>	<i><= Interact With =></i>	<i>Personal Dispositions Needed for Teaching and Learning</i>
• Reflecting • Analyzing • Grounding or informing work through research and/or theory • Bumping into and resolving aspects of disequilibrium • Bringing it all together—making sense • Exploring • Documenting evidence of the teaching/learning process • Learning from a community of learners that involves talking, listening, and observing • Being responsive and intentional • Being an advocate • Supporting and involving families • Being involved in the field • Continuing to grow and develop as a professional	1. Contexts: Social and cultural experiences of children and families 2. Practices: Daily interactions with children on social, emotional, and intellectual issues 3. Documents of Planning and evidence of learning 4. Beliefs, philosophies, and theories 5. Time and Effort for continual learning and explorations	• Confident • Open to new ideas • Cognizant, intentional • Valuing the inherent worth and dignity of each and every child • Caring • Inventive • Problem solving • Persevering

Ms. Arya: So what does it mean to have a rule? Won't the other children learn that rules can be broken with no consequences?

Ms. Lucia: Interesting point. No one else joined her on the table. So, I wonder if they noticed and if so, what they thought. Let's ask them at the closing circle time today.

Ms. Lucia is satisfied with the decision to ask the children but still wonders about Ms. Arya's question about rules. When should they be broken? Who gets to decide when a rule can or cannot be broken? She decides to call her mentor to talk about this more. During their phone conversation, her mentor asks questions as a way to provoke self-reflection and analysis. Some questions asked were: What do you think about your decision to attend to Sloan's behavior by

observing and staying in close proximity? Do you think that communicating more about your thinking would have helped Ms. Arya understand better "in the moment"? What does it mean for the teachers, the group of children, and established policies/practices to attend to an individual child's development? When there are conflicts between those aspects, who decides what route to take (one adult, a collaborative team, an adult leader, the children)? What else can be done to help Sloan develop confidence in her physical self?

While the questions were not resolved during their conversation, both Ms. Lucia and her mentor agreed that bringing up the situation next week at the monthly meeting of the entire preschool teaching team and their mentor was a great plan. The goal was to engage all of the professionals in this dilemma, as a way to make sense of this complex situation through multiple perspectives.

Analysis of Professional Dispositions Example

Ms. Arya's professional disposition (or way of being) was seeing and analyzing the context from the point of view of a "safety at all costs" advocate, along with a practice that models and values following the rules. Ms. Lucia's professional disposition (or way of being), on the other hand, was seeing the situation from her own beliefs about how to help the children grow. For Ms. Lucia, this meant that she needed to be open personally to investigating new ideas and watching for learning moments over time, while simultaneously monitoring and providing a safe environment for the children's learning explorations.

Both teachers were engaging in profession dispositions that allowed them to dialogue in order to understand the situation and the decisions that were made. Neither person just agreed to disagree, nor did they discount the other's perspective. For Ms. Arya, this incident bumped into her personal and rule-based sense of a safe play environment. As a result, Ms. Arya approached this dialogue as an opportunity to problem solve by attempting to remind or build consensus with Ms. Lucia about the established rules of safety as a necessity for learning. Ms. Lucia, on the other hand, bumped into the idea that there may be multiple ways of thinking about the situation. Initially, she took this situation as a way to intentionally value Sloan. But she found that she personally needed to be open to others' ideas. More specifically, she approached the dialogue with Ms. Arya, and subsequently with her mentor and the other teachers, as way to continue her own growth as an educator by seeking input and multiple perspectives. It was not for validation or reprimand; rather, it was for an opportunity to understand the situation better and to think about it in relation to future opportunities for children like Sloan.

Development of Professional Dispositions

Developing Professional Dispositions Through Personal Engagement

Being a high-quality early childhood educator is not a passive endeavor. It requires an active

approach to develop professional and personal dispositions that are valued by the field. As discussed previously, professional dispositions are critical to one's practice. However, positive personal dispositions are needed, as well. These personal dispositions may include processes, such as being persistent and persevering, problem solving, confident, open to new ideas, caring, and inventive.

As a way to develop professional and personal dispositions, early childhood educators can do the following:

- Seek information about contextual impacts on development and learning.
- Ask questions and seek answers through readings and mini investigations (for example, gather classroom data to help answer questions).
- Document their own and children's learning.
- Analyze situations and interactions to better understand the children involved.
- Set aside time each day to reflect on children, families, or the teaching-learning process.
- Share successes and challenges with others.
- Learn something new each day to personally improve themselves—not about teaching or children.
- Question their own beliefs and actions, looking for consistencies and inconsistencies.
- Advocate for children, families, and their own program's policies that support them.

Developing Professional Dispositions Through Collaborations

Teachers should not work in isolation; rather, they should move beyond their personal classroom to engage as a member of a community of learners. As a way to further their professional development of dispositions, they can encourage their colleagues to do the following:

- Push their thinking.
- Provide alternative interpretations.
- Observe others' teaching and have others observe their teaching; debrief.
- Engage in dialogue over common readings (books, scholarly articles).

- Advocate in greater community regarding the profession.
- Meet on a regular, continuous basis.

Developing Professional Dispositions Through Mentorship

Teachers should not limit their communities of learners to their immediate colleagues. They should seek out other professionals in the field who can mentor and help them to move to the next level.

Educators should seek out a mentor who is willing to do the following:

- Provide an outside perspective or additional resources.
- Give more one-on-one feedback.
- Challenge and help the teacher make sense about the interaction of the teaching–learning process.
- Ground the situation in theories of development and learning.
- Push, provoke, and help them wade through tensions and new understandings.
- Document and share the process of the teachers’ learning with the profession.

Benefits of Developing Professional Dispositions

Ultimately, professional dispositions lead early childhood educators to actively construct the meaning of their work and of their individual identity and voice as a teacher. The impact of finding such meaning is multifaceted in that it opens up space for questions about one’s teaching in a non-threatening manner; it provides a lens or way of viewing the children that affects the why, how, and what one teaches; it opens opportunities for more teaching and learning possibilities and flexibility; and it pushes a way of thinking and working that values the inherent worth of each and every child. In addition, these professional and personal dispositions are vital for modeling the learning dispositions and processes that children need.

PROFESSIONALISM

Professionalism means having and exhibiting the knowledge, skills, and qualities that characterize a specific profession. Early childhood education (ECE) has not always been recognized as a distinct profession but rather was seen as a natural extension of domestic work. As ECE becomes increasingly credentialized and ECE workers diversify, concerns about professionalism continue to grow. This entry examines the concept of professionalism and its specific implications in the ECE field.

Understanding Professionalism: An Overview

There are specific, identifiable characteristics that distinguish professional fields of work. The characteristics that are specific to a profession are used as

criteria for determining whether or not individuals who work within that profession exhibit professionalism. To understand the term *professionalism* requires first a discussion of the qualities that differentiate a profession from other types of jobs.

A *profession* is defined as an occupation that requires prolonged education and training. Some professions require other specialized qualifications such as licensure, ongoing professional development, or additional requirements. Choosing and pursuing a profession is sometimes referred to as a calling because often people who go into the work describe having been compelled to do so. Professions usually involve types of work that provide services that address and promote the well-being of others. Because of this focus on service to others, professions are often considered to be more altruistic than other types of work or occupations. The nature of professional work often creates certain societal attitudes toward the profession as well as the people who do the work. Society may view the work accomplished by people working in professions as having a significant value. Professionals are often respected and held in high esteem by members of the community because the work they do makes an important, positive impact on individuals or groups of people. A profession is often viewed not only as a vocation that is rewarding and meaningful to the people who receive the services but also as rewarding and meaningful to the people who perform the work as well.

Professions have additional attributes that set them apart from other types of occupations. One of these is a specialized body of knowledge that is specific to the profession. A specialized body of knowledge is the foundation of a profession because it informs the knowledge, practices, skills, and approaches used to prepare individuals to work within the profession. It can also be used as the criteria for distinguishing the quality of the work provided. A specialized body of knowledge is typically based in scientific research that has been performed over long periods of time. These ongoing research studies and findings result in an accumulation of knowledge, proven practices, and approaches that are used by the professionals within the field to

do their work and to try to achieve the desired results and goals of the profession.

To work in a profession requires the successful completion of extensive education and training that is based in the profession's specialized body of knowledge. Some professions have differentiated employment and staffing patterns that reflect a hierarchy of knowledge acquisition by levels of educational achievement. These educational levels typically range from a beginning level to a more advanced level with each requiring more knowledge, skill, and educational preparation. Individuals who want to work within a profession that has differentiated staffing patterns often may enter the profession at a beginning level and then make advances to higher levels of employment based on their advancement in their educational preparation. Credentialing and licensure requirements, which are based on levels of educational attainment and/or formal assessments of a person's knowledge and skills, often determine who may work in a specific profession, at what level, in what capacity, and with what degree of responsibility and decision making.

Professional organizations, professional bodies, or professional societies are organizations that focus on a particular profession, the individuals who work within that profession, and the public interest. Professional organizations are usually nonprofit and do not seek financial gain from the services provided to members. There is typically a membership fee to become a member of the organization. Some professional organizations have requirements for membership that may include a certain level of educational preparation and/or work experience within the profession. There are multiple advantages for a person to become a member of a professional organization. Membership fees often cover not only membership in the national organization but also state and local group affiliate memberships. Services provided by professional organizations may include receiving relevant publications published by the organization; journals that contain the latest research and current findings from experts in the field; listings and offerings of professional development

opportunities at the national, state, and local levels; discounted registration fees to conferences sponsored by the organization; networking opportunities with other professionals; career and employment services; and opportunities to become involved in committee work and leadership roles within the profession.

Professions have written professional standards that are developed by one or more of their national or state professional organizations or licensing boards. These professional standards are specific to the profession and include the knowledge, skills, dispositions, and qualifications that individuals must possess to be employed within the field and to be able to competently conduct the work. Professional standards include the values of the profession, the educational preparation and training needed to work within the profession, principles and guidelines for providing professional services, and the types of services performed by the individuals employed in the profession. Professional standards often determine entry into the field including who may become employed and at what level. Professional preparation standards typically provide guidelines for the amount and types of continuous education and professional development needed after initial employment in the field, what types and quantity of ongoing professional development are required to continue to deliver services, and the level of responsibility a person should be given within the framework of the work or services provided by the profession.

Professions develop and use a code of conduct or ethics that identifies and states the ethics, values, and principles that guide responsible behavior and practices within the profession. Codes of ethics provide guidelines for the education, professional preparation, and behavior of those who work in the profession. A code of ethics includes profession-specific evidence-based practices for ethical behavior and recommendations for how to address and resolve ethical dilemmas encountered by individuals as they carry out the work of the profession.

Professionals usually have some degree of autonomy, self-governance, self-regulation, individual decision making, and control over the practices and

services they provide. People who work in professions take responsibility for providing high-quality services that are based in the specialized knowledge, skills, and dispositions of their profession. Professionals have the autonomy to make decisions about important aspects of their daily work and to make reasoned judgments and considerations that impact the lives of other people.

Being a member of a profession and exhibiting professionalism means making a commitment to learn a specialized body of knowledge that may require extensive educational preparation. It means keeping current and acquiring ongoing knowledge and skills as continuing scientific research provides new information that is relevant to the profession. Professionalism means doing one's very best to provide high-quality services and work because the decisions one makes and the work one does impact the lives of individuals, groups of individuals, the community, and society. A person who exhibits professionalism has attained extensive educational preparation, possesses and uses a specialized body of knowledge, and follows the guidelines and practices set forth by the profession's code of conduct or ethics.

Professionalism in Early Childhood Education

Lilian Katz was among the first to propose that early care and education possesses the characteristics of a profession. Since that time the professionalization of the field of early childhood has continued to advance. In addition, there has been an expanding public awareness of the need for high-quality early childhood education programs and highly qualified, well-prepared early care and education professionals. Scientific research now provides evidence of the importance of the early childhood period in life and the impact that high-quality early childhood programming can make in promoting and enhancing young children's development, school readiness, and lifelong educational achievement. There have been changes in public perceptions and public policies regarding early care and education, as well as changes

within the profession itself. At no other time has professionalism in early care and education taken on more meaning than it currently does. Informed by new scientific knowledge of the importance of the first few years of life, early childhood education professionalism requires extensive knowledge of child development as well as exceptional early childhood teaching and program-related skills.

Membership in the National Association for the Education of Young Children (NAEYC) is one mark of professionalism in the field of early childhood care and education. Membership in NAEYC provides a support base and resources for maintaining professional practices and individual professionalism. Early childhood professionalism depends on a teacher's knowledge and understanding of the standards of the early childhood profession, which are outlined in the *2010 National Association for the Education of Young Children Standards for Initial and Advanced Early Childhood Professional Preparation Programs*. These standards identify the knowledge, skills, and dispositions crucial for early childhood teachers to know, understand, and follow in order to effectively teach children. The NAEYC Standards are designed for the early childhood education profession as a whole and are relevant across levels of educational preparation and formal degree levels from the associate to the baccalaureate to the graduate degree. The NAEYC standards are used in higher education professional teacher preparation programs, accreditation systems, state policy development, and program improvement planning. The standards reflect the differentiated staffing patterns common in early childhood education programs with differences in the depth and breadth of standards-based knowledge and skills expected at each level of early childhood professional preparation.

Professionalism means using and following the *NAEYC Code of Ethical Conduct*, which offers guidelines for responsible teacher behavior and provides a common basis for resolving the ethical dilemmas encountered in early childhood care and education. Early childhood teachers can refer to the core values and principles found in the code to guide their ethical responsibilities to children,

families, the community, and society, as well as to their colleagues and employers.

Professionalism in early childhood education means that teachers take responsibility for providing high-quality services that are based in the specialized knowledge, skills, and dispositions identified in the standards for the profession, the code of ethics, and the other documents that compose the accumulation of scientific research and knowledge that makes up the profession of early childhood education. Achieving and maintaining professionalism also means that early childhood teachers engage in lifelong learning. They seek out opportunities for ongoing learning opportunities that focus on the acquisition of current research-based scientific knowledge and how this knowledge translates into high-quality, developmentally appropriate, applied teaching practices and learning experiences for young children.

Early childhood professionals make significant contributions to the betterment of their communities through the impact they make through their teaching of young children. The value of the work early childhood professionals perform is immeasurable in that it will extend beyond the lives of the teachers and the young children and families they serve. Enhancing and promoting the optimal development and learning of young children touches untold future generations. Professionalism in early childhood education means being the best, most highly qualified, competent professional teacher that one can possibly be because what happens in early childhood classrooms can change the trajectory of children's lives.

PROGRAM EVALUATION

Program evaluation is defined as the systematic study of services, interventions, programs, and policies designed to improve the lives of individuals, children, families, and communities. A type of applied research, program evaluation efforts utilize qualitative and quantitative research methods and a variety of research designs including descriptive strategies, case studies, and quasi-experimental and randomized experimental designs. The goal is to collect, analyze, interpret, and report information about service delivery efforts or policies. This entry discusses the history of early childhood program evaluation efforts, approaches utilized in evaluating programs, and the reasons for conducting program evaluations.

The purposes of program evaluations may differ. Some evaluations focus on an examination of program processes or formative evaluation questions. Evaluations of this type may examine a variety of questions including the need for programs or services. Program characteristics, accountability, or resource utilization may be examined. Internal processes within the program, program management

and administration, and the quality of the implementation may also be central facets of the program studied. Other evaluations focus on an examination of the products or outcomes of programs or policies or on summative evaluation questions including cost effectiveness, progress in achieving goals and outcomes, and short- and long-term benefits.

History of Early Childhood Program Evaluation Efforts

Program evaluation as a field has grown since the Great Depression and the Great Society programs of the 1960s. During these times of great social and economic change, the federal government began to play a greater role in developing social and educational programs in an effort to combat a variety of societal ills including poverty, racism, violence, urban decay, and lack of educational opportunity. In the United States, there have been many prekindergarten program evaluation studies. Some of the best known program evaluations conducted of early childhood intervention efforts in the United States include the HighScope Perry Preschool Study in Ypsilanti, Michigan; the Abecedarian Project in North Carolina; and national studies of Head Start and Early Head Start.

Reasons for Conducting Program Evaluations

Program evaluations may be conducted to meet the requirements of funders, such as foundations and the federal government. A goal is to ensure money awarded to implement programs and policies is used effectively, judiciously, and in accordance with program or policy mandates. For example, as a result of the 1993 federal Government Performance Act, programs that are publicly funded are required to provide evidence of program effectiveness. Programs and policies are often enacted in a political context and as such, program evaluation data can sometimes be used to make decisions about the merit or worth of programs or policy changes. Data can sometimes

be utilized by funders to determine whether programs and policies should be continued, expanded, scaled back, or discontinued. This can create a difficult situation for evaluators and program personnel given that program data can sometimes be used to make high-stakes decisions about programs and policies.

There is also some controversy in the field about the type of research design and methods that should be used in establishing program impacts. Some view random assignment, experimental design studies as the preferred way of measuring and assessing the effects of programs or policies. In studies utilizing this design, potential program users or clients are assigned randomly to treatment and control groups, with program outcomes measured at program entry and exit. If the group receiving the intervention performs more strongly on the outcome measured than the control group, the assumption is made that the program or policy has been effective in producing positive changes in clients or program participants. However, causal linkages can be difficult to establish. It is also important to consider the quality of interventions, program utilization or dosage, and the characteristics of program participants in order to fully understand program outcomes or impacts.

There has been an increased emphasis on considering how program evaluation data can be utilized not only to meet funding requirements and demonstrate impacts, but as an opportunity for programs to gain important information that will enable them to become more effective. The term *utilization-focused evaluation* was developed by Michael Quinn Patton. It denotes evaluations that help to develop and study questions developed by program personnel and consumers. Utilization-focused evaluations can be used to better understand questions program personnel and clients have about the implementation of programs and program processes. Evaluations can be used to examine the strengths and weaknesses of efforts, and what modifications may be made to programs and policies to increase the potential for positive outcomes, informing other similar efforts that may be undertaken.

Further, the Joint Committee for Standards in Educational Evaluation has established standards for program evaluation. The standards highlight the need for program evaluation efforts to focus on utility or the practical needs of program users, use research methods that are realistic and prudent given the program's context (balancing technical rigor and adequacy), and legal and ethical propriety in programmatic research.

PROGRAM FORMATS AND SCHEDULES

Early childhood education has been recognized as a crucial component to later success in schooling and life. While this has been established through research and recognized in public policies, it is not yet fully realized in the structure of the education system. From birth through age 8, educational programs and formats vary greatly for young children and are not aligned with the education system. This is evident in the diverse early childhood programs and schedules that are part of the child care and pre-K structure. This entry provides a brief introduction to child care options, which include private child care, church-based preschool, preschool, family-based/home-based child care, Head Start/Early Head Start, public pre-K, and kindergarten programs, including half-day kindergarten (HDK) and full-day kindergarten (FDK).

Child Care

Child care is viewed as the supervision, nurturing, and educating of young children beginning at infancy and continuing on through age 4. It may be delivered by a home-based provider, simulating more homelike settings for children, or in a more formal, organized child care center. The formats of child care programs vary widely from provider to provider and from system to system.

Private Child Care

Families are free to choose between various private child care options available to them. In private centers, programs are as unique as the businesses that operate them. Child care centers usually accept children at 6 weeks of age (infants) through school age (before and/or after school programs). The formats may revolve around age-related rooms (infant rooms) or age-integrated areas (infant/toddler rooms). Each center determines how it will group children based upon population, space, need, staffing, state regulations, and curriculum.

Church-Based Preschool

Families may choose a faith-based program format where children are exposed to and education/nurturing revolves around a spiritual design related to the religious format of the church-based center. The schedules in such private settings usually include some religious teaching time in addition to developmental aspects, including physical, social, emotional, and cognitive domains. The formats of these programs vary extensively and families are usually offered multiple choices for the days and times their children will be in school. Church-based programs are private and the tuition is the responsibility of the family.

Private Preschool

In most communities, families can select among many private preschool programs. The formats of these programs are just as varied in their offerings of days and times of attendance as the aforementioned church-based programs. These schools are usually set up as a business or in connection to a business, so they try to meet the needs of the diverse families they serve.

Family-Based/Home-Based Child Care

Families may choose to place their child with a home-based or family-based provider. This is a child care location centered in a private home. Although these are privately owned centers, state regulations apply to protect all children and families involved. The schedule and program for the day is decided by the home-based provider and vary from home center to home center. Hours of the programs are often lengthy in order to provide care for working parents.

Head Start/Early Head Start

Provided to qualifying families, Early Head Start (EHS) serves the families of infants and toddlers under the age of 3 as well as pregnant women. Head Start (HS) continues that work with children ages 3 and 4. The program format and schedules

of each are established by EHS and HS and are similar in each location.

Public Pre-K

In some states, public preschool is available to children who qualify under guidelines of economic or educational need, but as of 2015, this was not a universal offering to children and families across the United States. As with most early childhood programming, public pre-K varies widely among states with some offering part-day programs and others offering full-day programs.

Kindergarten

Once children reach the age to enter kindergarten, variations in schooling continue. In the United States, kindergarten is viewed as a fully integrated part of the K–12 system, but in reality, it has yet to be fully integrated. On the one hand, kindergartens are supported by the infrastructure of the public education system (e.g., in terms of teacher licensing, including teacher certification, and payment compensation levels). On the other hand, kindergartens share many policies and practices with child care centers and continue to be guided by early childhood education philosophies. Notably, kindergarten policies vary widely from state to state with each state determining whether kindergarten is mandatory, the starting age of children, methods of funding, and the length of the school day. As of 2015, only 15 states require kindergarten. Although the opportunities and advantages of early childhood education have been noted, the alignment of kindergarten with the public school structure is only beginning to be realized.

Half-Day Kindergarten (HDK)

In the United States, many schools offer a half-day kindergarten program that permits children to attend school for part of the school day. Children may arrive for the morning program, usually attending for approximately 3 hours and leaving before lunch, or they attend the afternoon

session, arriving after lunch and leaving at the conclusion of the school day. Since the No Child Left Behind Act of 2001, many kindergarten programs have shifted to a more academic focus, primarily teaching reading and math skills. In half-day programs especially, time becomes an issue since academic mandates often replace more traditional and evidence-based practices such as dramatic play, blocks, and other sensory and motor activities.

Full-Day Kindergarten (FDK)

The schedule and program format of full-day kindergartens (FDKs) are largely up to individual school curricula and state mandates. There is no one rule on how kindergarten is delivered or to whom it is offered in the United States. Without a state or federal mandate, the variation of schedules and the format of the programs are limitless. Some FDK programs are based in academic curricula and first-grade readiness programs. The focus is on literacy and math with little attention given to the other academic areas or developmental domains. There are other FDK programs based on sound child development theories and play-based curricula. Best practice informs educators that children benefit from a program that is both academically challenging and based in sound child development theory.

PROJECT APPROACH

The project approach to teaching and learning is characterized by in-depth investigation of real-world topics usually studied by a class of children for several weeks. The approach offers the teacher practical strategies for planning in-depth study by a whole class group. The teacher has an important guidance role in developing a project with various lines of interest or subtopics for detailed study. Opportunities are designed for children to make choices about what to investigate. The teacher also guides the children in applying skills as they collaborate with classmates to represent their findings. The three-phase planning and evaluation strategy of the project approach is outlined in this entry. The strategy is formulated to provide guidance to the teacher for managing in-depth investigation.

Learning through projects has been advocated by many educational experts to stimulate interest in learning and to provide opportunities for children to learn firsthand about the real world in which they live. The project approach was described by Lilian G. Katz and Sylvia C. Chard in 1989 to offer a restatement of these ideas in the North American context to help teachers who were becoming interested in teaching through projects toward the end of the 20th century. Earlier proponents or examples of project work were found in the work of John Dewey, William Kilpatrick, Susan Isaacs, the British infant schools after World War II, the U.S. open education movement, and the schools of Reggio Emilia in northern Italy.

Preliminary Planning

The topic of study for a project is usually chosen by the teacher with the children's experience, interest, and prior knowledge in mind. The topic may arise out of class reading, the prescribed curriculum, or discussion of local events. Topics that have been found to be most productive are those relevant to the children's daily lives and interests. They are also chosen because they are deemed to

be worthy of children's time and energy in terms of the learning opportunities afforded. Topics may range from "how shoes are made" to "who works on a farm" to "where food comes from" to "how the children in the class get to school." These topics are studied in ways that help children better understand the world in which they live.

Preliminary planning by the teacher consists in thinking through the topic, considering possible lines of inquiry, and contacting experts who might offer field experiences or visit the classroom as experts for the children to consult. This initial planning is done by the teacher, who develops a concept map or topic web of related ideas and vocabulary. The teacher thus anticipates the various directions the study may take before discussing the topic with the children for the first time. The document resulting from this anticipatory process provides a practical reference to assist the teacher in recording the development of the project. In the elementary school, the teacher has to evaluate the topic in relation to curriculum requirements for the children in terms of the vocabulary they will be using, the conceptual challenges involved in understanding the main ideas, the opportunities to apply higher order thinking skills in both research and representational work, and the relation of the study to various subjects of the curriculum.

Three-Phase Planning and Evaluation Strategy

The teacher plans for each project to progress through a sequence of three phases. This three-phase structure offers a temporal framework for the study. It also provides the teacher with a narrative outline to account for the development of children's understanding of the topic both individually and as a group.

Phase 1

In the first phase of the project, the teacher shares a personal experience or shows the children an object associated with the topic to provoke discussion. The purpose of this introduction to the

topic is to awaken the curiosity of the children and develop their interest in it. The teacher stimulates discussion of relevant personal experiences they have had. Discussion times are scheduled over several days and the teacher notes different levels of prior knowledge the children have and areas of the topic in which they express particular interest. The teacher encourages children to wonder about the topic and helps them generate researchable questions to investigate over the following weeks. At this time, the representational work involves the children sharing their experiences in order to clarify their understanding. During this process the teacher notes gaps in the children's knowledge or misconceptions that can be addressed by research as the project progresses.

With the younger children, preschool to kindergarten, the parents can be involved in helping to stimulate interest in the topic by discussing it at home and encouraging the children to share their experiences with classmates at school. Parents can also be helpful in offering expertise in the second phase of the project, volunteering to accompany the class on a field visit or providing access to a field site. The first phase gives way to the second once a common baseline understanding of the topic has been achieved and a list of questions has been generated to guide investigative work.

Phase 2

The second phase begins with field work or the visit of an expert to the classroom to answer some of the children's questions. The children are usually eager for new experiences and new information to be provided at this time. Following early firsthand experience of the topic the children engage in representing the information they are most interested in. They may form groups and work together to clarify new understandings. New questions are added to the list to be researched, and books and online resources may be consulted according to the age of the children. The teacher may set up opportunities in the classroom for them to further investigate ideas they are curious about after the initial field experience.

Discussion continues to be an important feature of project work in the second phase. The teacher can set expectations for the work and help the children share their ideas and report the findings of their investigations. The opportunity for children individually or in groups to make choices about the directions their work may take means that they have to be responsible for informing their classmates of the progress they are making. While there are opportunities for children to work independently, all the work in the classroom is guided by the teacher so that children do not waste time or materials in unproductive activity when they need suggestions or support. When children find out for themselves through exploration, they usually take longer to represent information that is new to them than if they are told the answers to their questions by the teacher. However, when they can find out information over a period of time in a project they can become familiar with new ideas and see how they relate to knowledge of the topic as a whole. In this way, they can connect new information with that which was known earlier and develop deeper and more personally meaningful understandings.

Some of the work is done by teams of children and other work is done by individuals. This allows the teacher to guide children according to their individual interests and learning needs. One child may be working at a relatively simple level together with another child whose knowledge is more advanced. But both gain from collaboration as they each help each other in their own way. For instance, one child might hold two objects in position while another child measures the distance between them. In this way, any child's personal strengths may enrich the learning opportunities for any other child in relation to the project topic.

As the project progresses, all children are informed of the progress being made by other groups or individuals in the class. This is done through discussion where children report briefly on their work in progress and on work they have completed. There are opportunities for children to comment on one another's work and to perform the role of "critical friend" as they seek to improve

the quality of their representations. They also learn about the work going on throughout the classroom by means of displays of completed work that are posted to provide reference information for the whole class. Where project work is flourishing, the classroom is a place where visitors can see evidence around the room of what the children are interested in, what they are learning, and how it relates to standards of learning or experience, or curriculum goals where these are appropriate.

Phase 3

Once the children have completed most of the investigation, the teacher can review the progress of the project with the children and involve them in sharing their work with an outside audience. Others interested in seeing the work may be other groups of children in the school or center, parents, or those experts who have helped the class to carry out their investigations. Some of the ways children have shared their work have been setting up a museum (e.g., a rock museum), engaging in extended role play with a participating audience (e.g., setting up a restaurant or checking into a hospital), or offering a guided tour of their work (e.g., taking visitors on a tour of the garden they have worked to design and plant).

The activity involved in arranging to share their work in these ways involves the children in reviewing the highlights of their project, considering all they have learned, and celebrating their achievements. They become spokespersons for their own work and the work of their classmates. Teachers and parents initially unfamiliar with the project approach have commented on the confidence and awareness of detail the children show as they tell about research and show the representations of their findings. The projects are memorable for the children because they participate actively and uniquely in a meaningful collaborative venture.

Conclusion

Developments in brain research and the psychology of learning have led to increasing interest by educators in the project approach at the time of writing

this entry. It has also been noted that children tend to put more effort into schoolwork and tend to remember more of what they do when they have some choice in how the work is developed rather than learning in the same way as all others in the class through direct instruction. While some of the time in school has to be devoted to direct instruction of the whole class in order for older children to acquire academic skills, project work allows for the application of those skills by children in more informal learning contexts that have meaning for them. In classes of younger children where spontaneous play and sensory exploration support children's learning, the project work provides the more formal aspect of the program. Projects for children of any age allow them to develop their understanding of the value of academic skills in everyday life. Project work rarely comprises the whole of an educational program but has been found to provide complementary educational opportunities when used alongside other teaching approaches.

PROJECT SPECTRUM

Project Spectrum was a 10-year research initiative dedicated to the development of an innovative approach to assessment and curriculum for the preschool and early primary grades. Guided by David Feldman's conceptual framework of *non-universal development* and Howard Gardner's theory of *multiple intelligences*, Spectrum's work is based on the belief that each child exhibits a distinctive profile of cognitive abilities or a spectrum of intelligences. These intelligences are not fixed; rather, they can be enhanced by educational opportunities. The Spectrum approach to early education emphasizes the identification of young children's areas of cognitive strengths and promotes use of this information to design educational support appropriate to individual children.

The Spectrum Assessment for Preschool Children

The Spectrum assessment consists of 15 activities in seven domains of knowledge: Language, math, music, art, social understanding, sciences, and movement. Designed for use in preschool settings, the assessment aims at identifying diverse intellectual abilities that young children express when engaging in meaningful activities that use "intelligence-fair" materials, that is, materials appropriate for assessment in specific domains.

Of the 15 activities, some are structured tasks that can be administered by a teacher with one child at a time, including, for example, the dinosaur game, which assesses early math abilities, and the classroom model, which assesses social

understanding. Other activities can be used in a group setting, such as creative movement and drawing. Each activity measures specific abilities, often requires particular materials, and is accompanied by written instructions for task administration. The instructions include a score sheet that describes different levels of the key abilities used in the activity. The child's performance on many activities is quantifiable. During the assessment, the child's working style is also recorded. Working style refers to the way in which a child interacts with the materials of a content area, such as degree of engagement, confidence, or attention to details.

The results of Spectrum assessment are described in the form of a narrative report, called a *profile*. The profile is based on the full range of cognitive abilities examined through the Spectrum activities. Using nontechnical language, it describes each child's relative strengths and weaknesses in terms of the child's performance and working styles in different content areas. The focus is each individual child's capacities; only occasionally is a child described in relation to peers. For example, a child's unusual sensitivity to different kinds of music might be described by reference to his or her movement and attentiveness during and after listening to various music pieces. In addition to detailing a child's capacities, the profile also identifies the child's preferences and inclinations. Stressing the importance of ongoing assessment, the profile is not a static image but a dynamic composition of a child's interests, capability, and experience at a particular point in time. The conclusion of the profile typically includes specific recommendations to parents and teachers in terms of possible ways to support identified strengths and improve weak areas.

Spectrum Early Learning Activities

The Spectrum Early Learning Activities are curricular activities in eight content areas: language, math, music, art, social understanding, natural science, mechanical construction, and movement. Each area includes 15 to 20 classroom activities and several take-home activities appropriate for

children in kindergarten and first grade. The learning activities do not constitute a whole curriculum. Instead, they are designed to supplement regular curricula, to expand learning in nontraditional areas such as mechanical construction and social understanding, and to provide a structure for classroom observations in diverse content areas. The learning activities also can serve as catalysts, providing ideas to help teachers develop their own projects or find ways to teach children who are not responding to more traditional approaches.

The learning activities in each area are organized around key abilities that are essential to success in the domain. In the area of mechanical construction, for example, key abilities include understanding of causal and functional relationships, visual-spatial abilities, problem solving with mechanical objects, and fine motor skills. Teachers focus their observations on key abilities while engaging children in activities. Teachers focus on children's development of key abilities through an ongoing assessment process.

Regardless of the content area, all Spectrum learning activities (a) highlight and exercise key abilities in a designated domain, (b) involve hands-on problem solving in a meaningful context, and (c) provide information that helps teachers adapt their curriculum to better meet the needs of individual children. In terms of the activity format, some occur in free play whereas others are structured. To assist teachers with implementation, objectives, materials, and step-by-step procedures are described for each activity.

In summation, because of its strong theoretical framework and unique approach to assessment and curriculum development, Project Spectrum has attracted much attention in the field of early childhood education. The three published volumes documenting Spectrum's work have been translated into Spanish, Chinese, Italian, and Portuguese, and there are several dozen assessment instruments in the field inspired by the Spectrum work. Many early childhood teachers and schools endorse the Spectrum approach to early education and use it to guide the teaching and learning process in daily classroom practices.

The Spectrum work emphasizes diversity, individuality, and flexibility. It is best thought of not as a discrete program or a specific set of activities, but as a theory-based approach that emphasizes the importance of recognizing and nurturing a wide range of children's cognitive abilities. This approach can be used to help bring about important changes in educational assessment, curriculum development, and instruction.

PROSOCIAL BEHAVIOR

Young children demonstrate prosocial behavior when they voluntarily act to help, share with, or comfort another person. Examples include a 1-year-old child who picks up a book for a grandmother who dropped it, an 18-month-old who hugs her brother when he bumps his head, or a 3-year-old twin who gives his sister some of his

apple slices. These examples illustrate the three definitional characteristics of prosocial behavior: it is voluntary, intentional, and beneficial to another person. This prosocial behavior is striking evidence that even very young children recognize that the other person needs their help, understand what kind of help is needed, and take effortful action so that the other person benefits. In many but not all cases, young children's prosocial behavior is also unsolicited and unrewarded, a phenomenon that Warneken identifies as truly remarkable because without praise or reward and without checking to see if adults approve, the children perform behaviors to benefit others. The occurrence of prosocial behavior in very young children intrigues developmental researchers because it illustrates children's social cognitive ability to infer the needs of another person and to plan an action to resolve that need, and their early capacity for empathy and concern for the welfare of others.

The antecedents to prosocial behavior are evident in very young infants who show interest in another's distress. By 12 to 18 months, children have returned dropped objects to another person, helped put things away, and warned another person about danger. Sharing occurs as early as 12 months of age and increases in frequency by age 2, especially if toys are plentiful. Two-year-olds have been observed trying to comfort someone who is upset. Throughout the preschool years (3 to 5 years), children develop a growing repertoire of prosocial behaviors and use them with increasing frequency. They also become more skilled in matching their actions to the needs of the other person, as opposed to early prosocial actions that mimic how the child would herself prefer to be helped or comforted. As a classic example, 20-month-old Christine would comfort her older brother by sharing her comfort bunny, but by the time she was 3 years old, Christine understood that her brother needed a hug instead. An understanding of the ages at which early prosocial behaviors occur continues to shift with new research and refined empirical strategies, suggesting that these estimates are inevitably more accurate indices of what young children can do prosocially than of what they cannot.

Early research tended to treat each various example of prosocial behavior as representing the full class of prosociality and drew conclusions about all prosocial behaviors after actually assessing only one or two forms of behavior. However, more recent research has established that children do not behave consistently for different varieties of prosocial tasks. Instead, different prosocial behaviors are found to be distinct from one another and to have different correlates. Some prosocial behaviors occur more readily than others, presumably because of the complexity of the social judgments and the amount of donated effort that these require of a child. As one example, sharing is different from some prosocial behaviors because it costs children a portion of what they already possess and is more than simple compliance with another person's request. In comparison, prosocial behaviors that require effort but no loss (comforting or helping) occur more readily than sharing. More recent research examines the trajectory of a single example of prosocial behavior rather than generalizing from one distinct prosocial behavior to another.

Age alone does not explain individual differences in the prevalence of prosocial behavior in one child versus another. The occurrence of spontaneous helping and comforting behaviors in very young children prompted Hoffman to suggest that prosocial behavior is founded on a robust biological predisposition for helping. Indeed, twin studies have provided some evidence of the heritability of "prosocialness." Siegler, DeLoache, and Eisenberg posit that this may be due to genetically based differences in children's emotional regulation or assertiveness. Regardless of the cause, evidence from multiple sources suggests that some children are more prone to be prosocial than are others. Situational differences can also explain some of the variance in prosocial behaviors. For example, the more apparent the other's distress, the more concerned children are likely to become and the more likely they are to help. Parents influence their children's prosocial behaviors by modeling and espousing values related to caring and helping and by providing children with multiple opportunities to practice prosocial actions. Also, multiple researchers

have demonstrated children are more likely to behave in prosocial ways when their parents are warm, highly engaged, and authoritative. Older siblings also model prosocial behavior toward their very young brothers and sisters.

A generally accepted interpretation of early studies was that girls use more prosocial behavior than boys, but more recent studies suggest that gender differences are confounded with the method used to assess prosocial behavior. Bouchard and colleagues found gender differences only when comparing early childhood educator ratings of children's prosocial behaviors; no gender differences were found for direct observations of children's behaviors in a child care setting or for children's responses to hypothetical interpersonal problems. A current supposition is that boys and girls may engage in different prosocial behaviors, but neither gender is more prosocial than the other.

Prosociality is widely recognized as an early step on a trajectory toward social competence and engagement in later childhood and adulthood. Children who are more prosocial during the toddler and preschool years are subsequently more ready for school and more successful in the later grades. Prosociality among very young children is a significant predictor of supportive friendships in preschoolers, and positive friendships in older children. Moreover, preschoolers in friendships with highly prosocial best friends were more prosocial themselves when assessed two years later. Thus, very young children's participation in prosocial behavior is not only a remarkable accomplishment but also developmentally important for their subsequent life success.

PSYCHOSEXUAL THEORY

Theories of sexual behaviors exist in cultural lore. The ancient Hindu Kama Sutra describes a prominent societal role for sexuality and provides detailed prescriptions for seduction and erotic practices (Vatsayana, 1963).

Psychoanalytic Theory

Sigmund Freud (1939) pioneered a theoretical psychoanalytic framework to conceptualize psychosexual development. Infants go through

developmental stages, each of which is defined by an erogenous zone of the body—the oral, the anal, and then the genital—that is especially vulnerable and sensitive to stimulation. Young children derive sexual pleasure instinctually from each zone. Thus, the word *sexual* has a broader meaning in Freudian theory, since sucking, swallowing, and biting would be pleasures of the earlier and later oral stages.

According to Freud, successful navigation through these stages requires conflict resolution to enable a child to move on without undue frustration in any phase. An older baby needs to learn to suck without biting the breast and causing the mother to withdraw in pain and anger. The oral stage usually ends at time of weaning. If a child becomes fixated at one stage, then a portion of the child's psychic energy ("libido") is so invested that the child cannot move competently on to the next stage. For example, if toilet learning is punitive and coercive, the child may retain feces stubbornly and later develop what Freud termed an "anal retentive" (stubborn/stingy/hoarding) personality. Or a child may develop an "anal aggressive" personality, exemplified by temper tantrums, destructiveness, or cruelty.

Sensual self-pleasuring begins early. Babies suck their thumbs. During diapering, boy babies pat or pull at the penis; toddler girls find their vulvas with fingers. But, at about 4 to 5 years, genitalia become the *special* focus of pleasure. Children express curiosity about birth and genitals. During the "phallic stage," Freud (1939) postulated the predominance of the "Oedipus complex"—an unconscious wish by a boy to take the father's place as the mother's main love object. Freud pronounced this conflict to be at the "core of man's conflicted existence" (Erikson, 1968, p. 121). This conflict deepens as a boy develops an unconscious "castration anxiety," a fear that in retaliation for his wishes he may lose his penis.

Freud theorized that when boys begin to realize that they are never going to be in sexual relations with mother, they struggle to repress these Oedipal wishes, develop a superego, and then identify with father. Girls shift their initial love focus from mother to father (the "Electra complex") during the phallic

phase. For example, a preschool girl may declare cheerfully that she is "going to marry daddy."

Freud predicted lifelong effects if the Oedipal complex is not resolved well. Psychosexual disorders affect 1 in 4 adults (Maxman & Ward, 1995). It may seem that modern psychiatry confirms Freud's postulation of severe effects from a poor resolution of this struggle, given the extensive variety of sexual dysfunctions described in the American Psychiatric Association's *Fifth Edition of the Diagnostic and Statistical Manual of Mental Disorders* (DSM-5) (2013), which include delayed/premature ejaculation, arousal disorders, and sexual orgasmic dysfunctions. Paraphilic disorders include intense sexual arousal from voyeurism, exhibitionism, rubbing against strangers, sexual masochism/sadism, pedophilia, and fetishisms.

Freud believed that sex drives were dormant during the "latency period" from 7 to 11 but emerge again at puberty—Freud's final psychosexual stage, the genital—when adolescents struggle with sexual urges and must find ways to sublimate them and also ultimately find acceptable persons to love.

Eriksonian Theory

Erik Erikson (1968) enlarged Freud's psychosexual theory to include psychosocial development. He outlined a succession of eight stages, each involving a "nuclear conflict." The first two respectively involve development of trust versus mistrust and autonomy versus shame/doubt/rage. These conflicts must be resolved so that by weathering each crisis, the person can emerge with an increased sense of inner unity.

Erikson cautions against instilling too great a sense of guilt for when children handle genitals or manifest sexual curiosity. He writes that otherwise it may lead to a tendency "to follow any leader who can make goals of conquest seem both impersonal and glorious enough to excite an intrinsically phallic enthusiasm in men (and a compliance in women) and thus relieve their irrational guilt" (Erikson, 1968, pp. 121–122).

Erikson (1968) was concerned about cultural attempts to impose the "prototype of the lady" on

small girls. This involves a double standard: Girls are to repress any sexual desires, yet males will try to blacken a female's name through sexual gossip about her. At the same time there was a tacit and "equally ambivalent implication that any man who does not proceed to shed his gentleman's inhibitions when the opportunity of sexual conquest offers itself is a weakling who only deserves to be mercilessly provoked" (p. 65). Such early contradictory messages can lead to young girls' confusion and struggles to accept as valid their own sexual feelings.

Other Theorists

Having studied with Freud, Carl Jung (1928) later minimized the importance of sex in his personality theory and considered "libido" as life energy rather than sexual energy.

Karen Horney (1939) rejected Freud's theory of penis envy and instead retorted that men were envious of women's ability to become pregnant and mother children. She hypothesized that "womb envy" makes males drive for overachievement in work. She theorized that girls and women fear pain from penile penetration and possible vaginal injury. Horney rejected the view that the Oedipal complex has sexual origins, arguing instead that it arises as the result of a child's repressing any hostility toward his or her parents because a child deeply needs parental safe protection. In contrast, Melanie Klein (1975) theorized that repressed sexual curiosity is a chief "cause of emotional neuroses" (p. 30). When adults repress children's strong sexual curiosity, powerful tendencies toward repression are generated that also have "injurious effects" on a child's intellect (p. 29). Klein confirmed the strength of Freud's Oedipus complex in one little male patient with "an extraordinary aggressiveness toward his father and his clearly indicated passion for his mother" (p. 32).

Children, Gender Roles, and Parent Sex Role Socialization

Sex is biological; gender roles are constructed. Families emphasize sex role socialization early in

infancy (Honig, 1988, 2000). Sex differences in play styles appear from 10 to 14 months and are quite evident, across cultures, by the time children are 36 months of age (Wohlwind, 2012).

Judy Chu (2014), using relational theory—the idea that the self and the world are inextricably embedded within and influenced by "interpersonal relationships and social and cultural contexts" (p. 3)—spent two years observing and carrying out in-depth interviews with parents and preschool boys. She reported that young boys begin to define themselves as the opposite of girls due to fear of rejection by male peers and desire for acceptance by male peers. These motivations lead young boys to transition from being expressive and emotionally insightful to being aggressive and emotionally distant. Chu theorizes that boys reject what society views as naturally feminine qualities for what they consider more appropriate masculine ones.

Contrary to theoretical fears that psychosexual deviance arises when children are brought up by gay parents, researchers find that daughters of gay fathers are not less feminine in play than daughters of heterosexual parents. Gay fathers create a social environment in which more cross-gendered play and behaviors are encouraged rather than punished. Boys raised by lesbian mothers showed less gender stereotyping in play than boys in either gay or heterosexual families (Honig, 2015).

Conclusion

Contemporary views on psychosexual development lead to advice for parents and caregivers that providing gentle weaning, flexible toilet learning experiences, and calm willingness to accept children's occasionally intense sexual curiosity about bodily functions and how babies are made can reduce later chances for sexual neuroses (Honig, 2000).

PSYCHOSOCIAL THEORY

Psychosocial theory focuses on the development of self-understanding, social relationships, and one's relationship to society across the life span. The theory describes normal development as a product of the interaction of the biological, psychological, and societal systems. As such, it integrates multiple domains including cognition, emotion, sensory and motor abilities, and self-awareness—all aspects of children's development and learning. At each stage of life, development results from the ongoing interaction of the person and the culture, with particular attention to interactions within a circle of meaningful social relationships. The topics discussed in this entry include the definition and meaning of the term *psychosocial development*, the contributions of Erik Erikson to the development of psychosocial theory, key concepts in psychosocial theory, and contributions of psychosocial theory to early childhood education.

Definitions of Psychosocial Development

The term *psychosocial development* has at least three important meanings:

1. Humans are social animals. They have a variety of sensory, symbolic, and expressive capacities that support social interactions. In this sense, psychosocial development refers to the idea that human development takes place as a product of ongoing interactions of individuals with their social relationships.
2. The mind (psycho) and the society (social) are interdependent. In order for societies to survive and thrive from one generation to the next, they need to promote healthy, adaptive capacities in individuals. Knowledge and practices about how to socialize, nurture, and care for the young are passed from one generation to the next. In order for individuals to survive and thrive, they need to develop a sense of what is expected of them at each period of life and find ways to meet those expectations. In

this sense, psychosocial development refers to the idea that an understanding of development requires an analysis of the ways that individuals perceive and cope with cultural and societal resources and demands over the life span.

3. Finally, psychosocial development refers to the idea of an emerging view of self in society. This idea is captured most vividly in the concept of identity, a cornerstone of psychosocial theory. The theory suggests a transformative process through which the person gradually integrates an understanding of his or her own competences and values, and positions them in societal contexts. Self-awareness and self-insight are located in socially and culturally meaningful frameworks including gender, occupation, religion, family, political affiliation, ethnicity, and sexual orientation. Over time, the nature of this personal identity is forged, revised, and evaluated, leading to a sense of purpose and place in life.

Erik Erikson's Contributions to Psychosocial Theory

The basic framework for psychosocial theory is attributed to Erik H. Erikson (1902–1994). Erikson grew up in Germany. After high school, he traveled through Europe, studied art for a while, and eventually ended up in Vienna, teaching art at the Hietzing School, a private school for children of many of Sigmund Freud's patients and those who were studying at the Vienna Psychoanalytic Society. He studied the Montessori method in education and received a Montessori diploma. He was so talented in his interactions with children that Anna Freud invited him to join the Psychoanalytic Society, where he trained. He received a diploma from the Vienna Psychoanalytic Institute. Erikson studied the psychoanalytic approach while it was still a new, emerging field, much less structured and formalized than it was to become in later years.

While in Vienna, Erikson met his wife, Joan Mowet Serson, who became his lifelong collaborator. In 1933, under the growing threat of Nazi Germany, they moved to the United States, where

he became one of the first child analysts in Boston. Over the course of his career, he taught at Yale University; University of California, Berkeley; and Harvard University. In addition to his clinical work, he was influenced by American ego psychologists who focused on concepts such as mastery and competence motivation, the writings of Julian Huxley, who introduced him to the idea of psychosocial evolution, and leading anthropologists who involved him in studies with the Sioux Indians of South Dakota and the Yurok Indians of Northern California. In 1950, he published *Childhood and Society*, the work that provides the first detailed elaboration of his psychosocial theory. In that work, one can see the interweaving of his psychoanalytic training, his background in early childhood teaching, his clinical observations, observations of child-rearing practices in other cultures, a growing interest in ego development, his exposure to the historical events of the Second World War, and the influences of his life partner, whose language and artistic talents shaped the language and rhythm of the work.

Over the past 65 years, psychosocial theory has been influential in guiding research and theory in the field of human development. It is one of few theories that address development over the life span, taking into account the interdependence of individual and societal change. The theory has been expanded through the addition of new stages, the identification of central processes through which crises are resolved, development of measures to assess psychosocial maturity, and examination of the characteristics and diverse resolutions of specific psychosocial crises.

Key Concepts

Ego

Ego refers to a complex mental structure, present at birth, that strives to organize and interpret experiences. The ego uses a variety of coping resources including attention, memory, problem-solving skills, and insight in order to satisfy drives and find a balance among competing demands. The ego also strives to establish and

maintain social relationships, drawing on past experiences and an understanding of social expectations that frame interpersonal interactions. The ego is continuously changing and maturing, incorporating new experiences and adapting to both inner and environmental conditions, resulting in new self-understandings and new outlooks on relationships and society at each stage of life.

Epigenetic Principle

The *epigenetic principle* refers to a genetically guided blueprint or plan for development. The term is commonly used to describe patterns of biological or physical development in which the organism passes through a fixed sequence of stages, from seed or fertilized egg, through embryonic phases to the fully formed, mature organism. In psychosocial theory, the term refers to a predictable sequence of stages regarding changes in self-concept and relationships with others, indicating a time during which specific conflicts and capacities are especially salient. The full life span is required for the complete emergence of human capacities. The theory suggests that individuals anticipate future themes and revisit prior themes in order to arrive at an age-appropriate integration that permits forward movement through the stages.

Radius of Significant Relationships

Age-related demands are communicated through interactions with significant others. Over time, the nature and complexity of this network of significant relationships changes, bringing with it diverse messages about cultural expectations and demands. The network of significant relationships influences patterns of care, sharing of information, potential models for identification, and communication about culturally and socially valued attitudes, beliefs, and life goals. Interactions with others in this radius of significant relationships produce cultural variations in how the epigenetic sequence of stages will be experienced but are not thought to alter the underlying themes or the sequence itself.

Psychosocial Crisis

Psychosocial crisis refers to the tension or stress that is experienced at each stage of development as the person strives to meet society's demands and expectations. These demands vary from stage to stage; they may be for greater self-control, new levels of skill development, greater commitment to life goals, or new capacities for interpersonal bonds. At the beginning of each stage, the person experiences a discrepancy between his or her developmental skills and abilities, and the expectations of society to reach a new level of ego maturity. It is this discrepancy and efforts to resolve it that produce a sense of tension that is gradually resolved.

The theory presents the crises as polarities between a positive and a negative resolution, suggesting the underlying dimension along which the crisis is experienced. Both the positive and the negative poles of the crises are normally experienced as the person strives to meet societal demands. The theory hypothesizes that this tension and conflict are necessary features of development, produced by a combination of societal pressures and individual motivation for mastery and social integration. When the crisis of a stage is resolved with a favorable balance between the positive and negative poles, a prime adaptive ego quality is strengthened, providing important resources for coping with life's challenges. When the crisis is resolved with a balance that emphasizes the negative pole of a stage, a core pathology is strengthened, leading people to withdraw from social interactions and become increasingly guarded, and restricting resources that support mastery in subsequent stages. See Table 1 for a summary of psychosocial crises, prime adaptive ego qualities, and core pathologies at each of 10 life stages.

Although Erikson readily acknowledged his intellectual debts to psychoanalytic theory and training, psychosocial theory evolved into a distinct analysis of development. The following four features of the theory are of special note:

1. Ego capacities continue to mature and adapt over the life span.

Table 1 Psychosocial Stages, Crises, Prime Adaptive Ego Qualities, and Core Pathologies

<i>Psychosocial Stage</i>	<i>Psychosocial Crisis</i>	<i>Prime Adaptive Ego Quality</i>	<i>Core Pathology</i>
Infancy	Trust vs. mistrust	Hope	Withdrawal
Toddlerhood	Autonomy vs. shame and doubt	Will	Compulsion
Early School Age	Initiative vs. guilt	Purpose	Inhibition
Middle Childhood	Industry vs. inferiority	Competence	Inertia
Early Adolescence	Group identity vs. alienation	Fidelity to others	Dissociation
Later Adolescence	Individual identity vs. identity confusion	Fidelity to values	Repudiation
Early Adulthood	Intimacy vs. isolation	Love	Exclusivity
Middle Adulthood	Generativity vs. stagnation	Care	Rejectivity
Later Adulthood	Integrity vs. despair	Wisdom	Disdain
Elderhood	Immortality vs. extinction	Confidence	Diffidence

2. The theory focuses on the dynamic interaction of the ego and the social and cultural environments, suggesting diverse pathways from childhood through adolescence and later life.
3. The theory emphasizes strengths and vulnerabilities as complementary aspects of healthy, normal development from infancy through elderhood.
4. The theory suggests a process plasticity, recognizing that as people mature they can reinterpret or compensate for difficulties at earlier periods.

Contributions to Early Childhood Education

Many of the concepts of psychosocial theory are aligned with the principles of developmentally appropriate practice. The theory suggests a pattern and sequence of emerging ego strengths, including the positive and negative poles of each psychosocial crisis, the prime adaptive ego qualities, and the core pathologies, that help to frame expectations about the direction of social and emotional development in early childhood. The first three stages in

particular and their related psychosocial crises, trust versus mistrust, autonomy versus shame and doubt, and initiative versus guilt, suggest key themes for social and emotional conflicts. When combined with an understanding of cultural and community values, these themes have implications for the creation of positive environments for young children.

As a classroom teacher and as a clinician, Erikson drew heavily on his observations of children. From this work, Erikson developed a deep appreciation for the nature of children's imaginary play. Erikson suggested that play provides a context in which children express and solve psychosocial conflicts. In play, children can create the problem that is troubling them, and also impose a solution, thus resolving the tension of a difficult situation. In play, children can experience mastery, explore adult relationships, and create imaginary play companions who can express feelings or actions that the child has learned to inhibit.

Many early childhood educators are involved in the education and training of preservice teachers. The concept of identity development, a central theme of later adolescence, is a key factor in college student development. Students who express an interest in early childhood education are likely

to be striving to integrate their personal values, past identifications, and future goals into a coherent personal identity. Knowledge of psychosocial theory and the identity process are essential for guiding students to reach authentic, well-integrated decisions about educational and occupational commitments.

The life span focus of psychosocial theory suggests issues for the development of early childhood educators as well as for young children. The theory emphasizes the interdependence of individuals at various stages of life. Children do not raise themselves; they are nurtured, educated, and inspired by parents, older siblings, grandparents, teachers, and mentors. The psychosocial themes that are important to adults have implications for the quality of interactions between adults and children. For example, efforts to resolve the crisis of generativity versus stagnation may lead mature teachers to ask themselves if they are making meaningful contributions to their community through their teaching. Professional development of educators and approaches to parent education are often informed by an understanding of psychosocial development

and its application to healthy ego development in adulthood.

QUALITY

The concept of *quality* is used frequently in reference to children's care and education programs. Typically the usage denotes programs as being, or not being, high quality. This entry describes how quality is tied to many different aspects of programs. Additionally, how the concept is defined or used in different ways by researchers, policy makers, and early childhood professionals is explained. Finally, the entry addresses how the concept of quality has been critiqued.

Defining Quality

The colloquial definition of *quality* comes down to this: Quality programs are those that benefit young children's learning and development. While quality is widely employed as a concept, it has not been defined in readily available, clear, and precise ways. Rather, there have been various perspectives and purposes to discussions of quality.

For many researchers and professionals in the early childhood field, the concept of quality is rooted in research about child care. Initial research was spurred by questions about whether child care was harmful to children, and it was largely conducted under the umbrella of applied child development. Thus, the well-being of children became the end-point concern. Not surprisingly, variations

in what child care looked like were quickly revealed. Investigations then focused upon aspects of out-of-home care that were related to more beneficial outcomes for children. Examinations of aspects of care that could be said to represent quality, or the lack thereof, became the focus. Influential research included a major study of child care, beginning in infancy, conducted by the Early Child Care Research Network (sponsored by the National Institute of Child Health and Human Development), the Cost, Quality, and Outcomes Study, and the Head Start Family and Child Experiences Study (FACES).

From the 1980s onward, a rich body of research was generated through these and other studies. Generally, research has suggested that the benefits of higher quality child care to young children span across the social-emotional, language, and cognitive areas. This record of research, both its evolving agenda and thrust, and the findings, have solidified the concept of quality in the early childhood field.

Components of Quality

The research base, alongside policy and practice, has resulted in a perspective on quality that encompasses several different components. These components have received more or less attention from researchers and have been embodied differentially in policy efforts or practice guidelines.

Group or Classroom Structure

How groups of children or classrooms are structured has been an early and consistent focus of attention. Most consideration has been directed to the size of the group and the ratio of children to adults. Research has generally supported the relationship between smaller group sizes and fewer children per adult and more positive outcomes for children.

Staff Qualifications

The background of both teachers and administrators has been generally found to support better outcomes for children; the result has been an increasing focus on specific training and support for administrators as well as a focus on increasing expectations within the field for teachers to have college-level education specifically tied to early childhood (note that this could be a bachelor's degree, but also an associate's degree or a number of credits within early childhood).

Along with group structure, staff education and experience have also been widely studied, as well as embedded in policy. As a group, these components (frequently referred to as structural quality) represent quality in ways that can be regulated through policy and used in quality rating and improvement systems (QRISs) to spur programs toward higher quality.

In addition, program accreditation efforts, such as those administered by the National Association for the Education of Young Children and other groups, include expectations for structural quality that are often more stringent than state-level oversight bodies.

As the theoretical base for quality has developed, structural components of quality have been hypothesized to set the stage for what happens in classrooms among the teachers and children. Thus, smaller groups, with fewer children per teacher, adept administrators, and teachers with specialized education allow for processes in the classroom that have become a crucial focus for conceptualizing quality.

Interactions

Interactions have been a major focus of the research work on classroom processes. Quality

interactions between adults and children have been described as positively focused, sensitive and responsive to children, and individualized to meet their developmental and learning needs, based upon the research.

Generally, only a small number of methodologies for examining what happens in classrooms have been adopted for policy and practice. One, the Environment Rating Scales (ERS), said to assess global quality, is discussed later in this entry. The second instrument, which has rapidly gained stature in conceptualizing quality, is the Classroom Assessment Scoring System (CLASS).

CLASS instruments focus separately on infant, toddler, prekindergarten, and kindergarten through third grade groups. They share an orientation in which quality interactions are conceptualized as consisting of three domains: the emotional support provided by teachers (e.g., responsiveness to children's perspectives, emotional connections, sensitivity), the organization of the classroom (e.g., effective behavior management, the ability to maximize time for learning and the children's engagement), and the instructional support of teacher's interactions (e.g., developing concepts, facilitating language, and using effective feedback). The CLASS is now used for program monitoring in the federal Head Start program and in some states' QRIS structures for child care.

With the CLASS there is a greater focus on teaching and learning interactions than was previously evident within policy arenas. In addition, more specialized focus by researchers on particular components of interactions, such as literacy or math teaching and learning, has grown in the field. The impact of these lines of research is realized more directly in the area of curriculum development. With regard to practice, program accreditation bodies have varying emphases on interactions that both reflect the importance of interactions in the field's perspective on quality and act to further fix the concepts as integral to quality.

Arrangements for Learning

The consideration of processes within classrooms points also to the role of arrangements for

learning provided by components such as the materials provided to children, the physical environment, and the scheduling of activities. Each of these components may provide a range of opportunities and affordances for the processes involved in education and care.

This particular component of quality has been highly influential in policy and practice because of the heavily used Environment Rating Scales (ERS). The family of ERS instruments includes the Infant/Toddler Environment Rating Scale, the Early Childhood Environment Rating Scale, the School Age Care Environment Rating Scale, and the Family Child Care Environment Rating Scale. The ERS instruments are intended to assess “global” quality of classroom processes. The various subscales include the physical environment, curriculum and materials, routines and care, schedule and structures, interactions, and parents and staff.

The Early Childhood Environment Rating Scale was revised in 2014, with one aim being to strengthen the capacity of the instrument to predict child outcomes. Among the revisions are the addition of more items related to literacy and mathematics and a greater focus on interactions among children and teachers, which leads to some de-emphasis on provision of materials and arrangement of space.

The ERS instruments have been heavily used by researchers, particularly during the growth of research in quality described previously. Additionally, they play a prominent role in many states’ QRIS processes and have been promoted as a tool for program self-assessment. Their wide use, easy availability, and wide range of types of items have resulted in the ERS instruments being a dominant influence on perceptions of quality.

Curriculum and Approach

The components of quality discussed thus far have been the most influential in the work of researchers and policy makers. In these areas, instruments have been devised for research, and some of these have been transferred to the policy arena to support efforts to define levels of quality and facilitate quality improvement work.

There have been research efforts to examine early childhood curricula in relation to children’s outcomes. However, linkages between curriculum and quality-focused policy are not dominant in the United States. There are a number of different approaches to curriculum, and the market system has resulted in many easily available products. Policy may set some conditions for curriculum choice, such as Head Start standards that call for a “research-based” curriculum. However, curricula are not typically identified as either reflecting high quality or lacking in quality.

On the other hand, curricular approach is highly tied to notions about quality within the profession via definitions of best practice. For example, through three iterations, the National Association for the Education of Young Children’s (NAEYC) developmentally appropriate practice (DAP) guidelines have coupled quality of children’s experiences to particular forms of curriculum practice. Throughout all versions of the guidelines, quality education and care have been linked to knowledge about child development theory and individual children. In the second iteration, context and culture were added to these “starting points.” The original document was strongly constructivist in orientation, with more emphasis on guided instruction in literacy and mathematics added in later editions. In NAEYC’s 2009 position statement on DAP, the guidelines promote the importance of scaffolding children’s learning in consideration of research-based delineations of typical learning sequences. Children’s content-based learning and a focus on achievement gaps have grown in importance as reflected in best practice guidelines, thus impacting perceptions of quality.

Early Learning Guidelines

Early learning guidelines, or standards, are a rather recent, but now firmly rooted element of policy and practice in early care and education. From state to state, guidelines vary tremendously in how they are written—more or less detailed, structured around content disciplines or developmental domains, and inclusive or not of examples of teacher practices. What they hold in common are expectations for

children's learning and development. Underlying early learning guidelines is the belief that high-quality practices in early care and education are promulgated by intentional teaching decisions. The guidelines serve to support those decisions and thus are viewed as promoting quality.

Continuity

Research has linked lower turnover and higher wages to higher quality experiences in classrooms. While difficult to translate to large-scale policy change, these findings have been central in advocacy efforts. Continuity, reflected in longer term placements of children with teachers, has been advocated as reflecting quality, although the research here is limited.

Critiques of the Quality Concept

As has been evident in this discussion, researchers and policy makers have had great impact on the development of ideas about quality. There is concern that the voices of other stakeholders, such as families and children, have been relatively unheard.

Others have pointed out that the emphasis on measuring quality has led to a focus on average, or typical experiences. The concern here is that each child experiences an early care and education setting individually; the setting characteristics and processes that lead to one child's high-quality experience may not operate the same for another individual.

Because research has tended to produce universal definitions of quality and policy that have tended to be prescriptive, some have pushed back against these processes. They argue that this work stems from unexamined values and promotes normalization of these ideas without critique within the field. One question is, for example, what role local values and concerns can play in the dialogue about quality.

QUALITY RATING AND IMPROVEMENT SYSTEMS

A quality rating and improvement system (QRIS) is an organized method to assess, improve, and communicate the quality of early childhood programs in centers, schools, and home-based settings. QRISs are a relatively recent state policy innovation, beginning in the late 1990s. States have been regulating programs for children for more than a hundred years and have been expanding public investment in preschool programs for many decades.

The basic concept is to create standards that define several “steps to quality” from the baseline in each state (regulations) up to high quality (as determined by each state), deliver supports and incentives to providers to improve their quality, and widely publicize the ratings so consumers can make more informed choices. This concept is somewhat similar to ratings of products by Consumer Reports or AAA ratings of hotels or restaurants.

Background and Context for QRISs

At the heart of a standards-based system of early learning and development are three sets of standards that are most effective when connected and aligned.

Learning and development standards for children—often called “early learning guidelines” that describe children’s learning across content areas and progress in domains of development

Practitioner standards—the core knowledge and competencies that qualify adults to work with young children, expressed as credentials (degrees, certificates, licenses) that vary by program type and funding source and are often presented together as a career lattice

Program standards—the criteria that permit programs to operate (licensing rules) or receive certain funding (state prekindergarten standards, Head Start/Early Head Start Program Performance Standards) and standards that define good to excellent practice such as national accreditation and the progressive levels of a state’s QRIS

QRISs can harmonize and unite the range of practitioner standards and program standards and put early learning guidelines into practice. They also have the potential to promote reflective teaching practice and continuous quality improvement in all types of early learning and development programs.

Why QRISs?

QRISs developed in response to several facts.

- There is overwhelming evidence that children’s early experiences in families and communities have profound consequences for later success in school and life. The quality of early experience matters.
- Many young children are in organized programs, primarily child care, long before they enter kindergarten.
- Child care is a market that does not naturally produce high quality. Demand for quality is limited by both family ability to pay and lack of

comparative information on program quality. Price competition among suppliers keeps their quality investment low.

- Most programs for young children are of unknown quality, with the exception of those that meet national standards such as the Head Start standards or those of accreditation bodies such as the National Association for the Education of Young Children.
- Regulatory systems are not primarily focused on quality, but on minimum standards intended to define the threshold for legal operation in a jurisdiction.

When Did QRISs Begin?

Recognizing these facts, states began to define levels of quality between the state’s licensing rules and national quality standards to provide a pathway for improvement for programs and a measure of quality that can be reported publicly to inform consumers. The earliest states to develop statewide QRISs—Oklahoma in 1998 followed by North Carolina and New Mexico in 1999—embedded these levels of quality in their licensing rules, thus ensuring that all programs subject to state regulation were included in the QRIS. Later, states developed voluntary QRISs that build upon but are separate from regulation.

What Defines a QRIS?

Analysis in 2005 of the first 10 states operating QRISs revealed that these state systems had a common structure of five elements. These elements have become the basic definition of a QRIS.

1. *Standards* describing progressive levels, usually three to five, from basic licensing standards to high quality as defined in each state
2. *Accountability*, including assessment of compliance with the standards based on document review, and on-site observations using valid and reliable tools such as the Early Childhood Environment Rating Scales (ECERS), more recently Classroom Assessment Scoring System (CLASS) that lead to ratings (levels)

3. *Quality improvement supports for programs and practitioners* promoting participation in the QRIS and offering technical assistance and mentoring for programs to improve overall quality and coaching and professional development for staff

4. *Financial incentives* supporting the increased cost of producing high quality; including one-time awards for physical improvements (minor renovation, equipment, etc.), ongoing regular quality awards pegged to quality level, awards keyed to staff qualifications to increase compensation, and incentives designed to increase the proportion of low-income children in higher quality settings

5. *Communication and outreach* about the QRIS itself encouraging program participation and increasing awareness by consumers and publicity of the ratings once reasonable participation is reached so that consumers will be able to find quality programs

A QRIS is an intentionally transparent definition of the progression of program quality from basic to excellent. The design challenge is to clearly state the progression of quality (the continuum of quality improvement), while keeping documentation efficient and manageable for all types of participating programs, and for the state and others operating the system.

The heart of a QRIS is its standards, which represent a combination of evidence-based criteria, items that are important to consumers such as teacher years of experience, and items that have particular relevance to the population in a given state such as development of dual-language learners. The most common major categories of standards across contemporary QRIS are

- staff qualifications, including the credentials in use in the state;
- learning environment, teaching, use of early learning guidelines;
- family engagement; and
- management and leadership, including administration and support for practitioner reflective practice.

Group (or class) size and the ratio of adults to children are both strongly related to measures of program quality and to improved child outcomes. States that have group sizes and ratios that are unfavorable to children (or not included) in their licensing rules often place group size and ratio in their QRIS standards. This is especially true if the political and regulatory process of directly improving the content of state regulations has been difficult (or impossible). For example, over time in one of the earliest QRISs in a state that incorporates licensing rules as the bottom level, the licensing rules have been able to be raised when the large majority of programs at the first level of the state QRIS were able to meet the QRIS level above them. This has happened twice so far, much improving circumstances for children.

How Are QRISs Structured?

There are three common QRIS structures: (1) blocks, (2) points, and (3) hybrid (or combination). The earliest QRISs all used a block structure. More recently states have begun to develop or redesign QRISs as points or a hybrid. In 2014, the rough split among states' QRISs is that half have a block structure, about a quarter have a points system, and about a quarter use a hybrid system.

Block structures require all items at one level across all categories to be met before advancing to the next level. Blocks are based on the concept that quality is cumulative and progressive; this structure assumes that the quality and characteristics of programs on the same level are fairly similar. This is believed to be easiest to communicate to consumers because it is most like other rating systems, such as those for hotels.

Points systems, on the other hand, are based on the concept that quality can be expressed in a variety of ways based on a program's strengths. Providers desire to show their unique strengths and families appreciate the more specific information. The categories of standards express the overall definition of quality. Each criterion is assigned a number of points. Generally, to assure some equivalence within a given quality level, points

systems require that points be earned in each category of standards. The total points earned across all categories determine the level.

More recently developed QRISs have combined these approaches into a hybrid model, sometimes called a combination model. Generally the lower level(s) are blocks (all criteria must be met) and points are earned across categories to reach higher levels. Or certain items must be met (points earned). This structure reflects the belief that the basics of quality (the blocks, or required items) are necessary conditions that should be achieved by all programs. The other aspects of quality are expressed more individually by a program. Consumers can see that all programs have met basic standards and then search for those programs that match their needs and desires for their children.

A few states that have block structures report to consumers the highest level achieved in each major category of standards as well as the overall rating. The overall rating equals the highest block level that is achieved in all categories. This retains the block structure while providing more information to the consumer.

Recent Developments in QRISs

QRISs have spread rapidly from state to state through an osmosis-like process that has been effective because the concept of rating is straightforward and familiar, and the concern about school readiness and the quality of ECE has taken on higher public importance. In 2005, 10 states were operating a statewide QRIS and 25 states were in some stage of exploring, planning, or piloting. By 2014, there were 38 states operating a QRIS, 12 in some stage of development, and only one state without any QRIS activities. By contrast, the first wave of states establishing state-funded prekindergarten programs began in the 1960s and more than 50 years later there are still 10 states without such programs.

State development of QRISs was recognized in 2011 by the federal government in the first Race to the Top Early Learning Challenge (ELCG) grant competitions. The ELCG laid out five key reform areas, one of which was “Defining High-Quality,

Accountable Programs by creating a common tiered quality rating and improvement system that is used across the State to evaluate and improve program performance and to inform families about program quality.” The term *tiered QRIS* was used to reinforce that a QRIS is a set of progressive quality standards, rather than one standard.

QRISs Moving Forward

The QRIS National Learning Network (QRIS-NLN) began in 2009 to provide a forum for exchange among national and state leaders and sponsor a website and an annual meeting focused on QRIS policy and practice. Research on QRISs has expanded with support from the federal Office of Planning Research and Evaluation in the Department of Health and Human Services via a network of researchers called INQUIRE. One result is the 2010 *Compendium of Quality Rating Systems and Evaluations*. In partnership with the QRIS-NLN, the QRIS Compendium is now a searchable online database.

Newer QRISs are not just focused on child care but intentionally include all settings for young children, for example, Head Start, prekindergarten, and public schools. Most QRISs are reviewed and revised every 3 to 5 years to incorporate new knowledge, streamline processes, focus on more powerful predictors of later child outcomes/school readiness, and better function as a common accountability system for all funders. QRISs appear to be firmly embedded in state policy.

QUALITY THROUGH COLLABORATION: OKLAHOMA'S QUALITY INITIATIVES

Oklahoma is considered to be the first state to create a comprehensive statewide quality rating and improvement system (QRIS) for early care and education with the creation of its Reaching for the Stars initiative in 1998. This entry discusses initiatives that began in the early 1970s and led to the state's QRIS. These initiatives have provided, and continue to provide, smooth pathways for individuals to grow as professionals in the field of early care and education.

Betty Stratton, a child development specialist at Oklahoma State University Cooperative Extension Service, began work in the early 1970s on a professional development plan for child care staff in Oklahoma. At this time, child care was becoming an important aspect of the U.S. economy as an essential service for families. Oklahoma's licensing standards for child care providers required that they have a high school diploma or its equivalent. There was no ongoing training for staff and directors in the 1970s. Over the next 30 years, Stratton and others

developed Oklahoma Training for Child Care Careers, which eventually became a nonprofit entity called Child Care Careers Inc. A statewide advisory committee, with representatives from all sectors of the early care and education community, was brought together to identify needs of child caregivers and effective strategies for training child care staff.

Stratton was the first author of a child care course of study and other authors were identified to create additional courses that included caregiver and trainer guides for each course. Volunteer trainers were identified to teach each 10-hour course. Criteria for trainers and a system for approving trainers were created. At completion, caregivers would have enough hours to obtain a Child Development Associate (CDA) national credential. By 1998, there were about twenty-six 10-hour courses for child care staff, 10 courses for family child care home providers, and specific courses for center directors. Funding was provided by the Oklahoma Department of Human Services—Child Care Division (OKDHS) as it was designated the lead agency in 1991 to administer the newly federally funded Child Care and Development Block Grant (CCDBG). In 1998, Child Care Careers, Inc. was integrated into the Center for Early Childhood Professional Development at the University of Oklahoma.

In addition to the work of Child Care Careers, Inc., resource and referral agencies in Oklahoma opened in the greater metroplexes of Oklahoma City (Rainbow Fleet) and Tulsa (Child Care Resource Center) in the late 1970s. The agencies served family child care home providers with a mobile toy lending library and families with information on locations of child care in each community. Currently, the Oklahoma Child Care Resource & Referral Association oversees eight regional branches whose purpose is to provide accreditation resources, training, and support for child care centers and family child care homes in rural and urban areas.

Focus on Diversity

As professionals in the field of early education continued to examine ways to improve early education, Ruth Ann Ball and Mary Lou Acers initiated meetings of interested professionals to learn about

and reflect on their understandings of diversity. The series of meetings was followed by a weekend retreat in 1992 for interested faculty and teachers of young children to discuss ways of becoming more inclusive in their teaching of adults and children; it was attended by 40 early childhood higher education faculty and teachers of young children. The Oklahoma Association for the Education of Young Children, the Southern Early Childhood Association, the Federation of Jewish Women, and the State Department of Education provided funding for the retreat. Louise Derman-Sparks's anti-bias curriculum approach was utilized to raise awareness of personal biases and strategies for inclusion in teaching. Outcomes of the meetings and retreat included greater awareness of diversity through changes in college course syllabi, the first diversity conference in the state, greater acceptance and inclusion of all cultures in early care and education settings, conference presentations, and efforts to make sure professional boards include a diverse membership.

Beginnings of Universal Pre-K

Ramona Emmons Paul began work in the Oklahoma State Department of Education in the early 1980s to implement a pilot preschool program for 4-year-olds in 10 Oklahoma public schools. This project required that Oklahoma policies be changed to monitor early childhood classroom size and curriculum content. Ultimately, this pilot led to the nationally known universal half-day pre-K program in Oklahoma for 4-year-olds in public schools. Environments appropriate for young children and early childhood teacher certification are required for all of the state's pre-K classrooms. Bridges are still being developed among the multiple systems that exist for early care and education for children from infancy through age 8 in Oklahoma: child care, Head Start, and public schools.

Moving Forward to Strengthen Staff Qualifications

The early childhood education and care professional development movement expanded in the

1990s with a team of eight early childhood professionals representing the Oklahoma Department of Human Services, the state Department of Education, resource and referral agencies, community colleges, 4-year colleges, universities, and the Oklahoma State Career Technology Office. These individuals were tasked with improving the quality of child care centers and family child care homes and building on the Oklahoma child care careers work that began in the 1970s. At the same time that Oklahoma was involved in this initiative, the National Association for the Education of Young Children (NAEYC) held its first professional development institute in Los Angeles, California. At this institute, early childhood professionals from Wheelock College shared a perspective of the vision for professional development for the entire country. The core group of early childhood professionals working to strengthen professional development in Oklahoma met to create a vision statement for early education in the state. The vision statement was adopted by the state's Early Childhood Professional Development Team.

Our vision for the early childhood profession in Oklahoma is that all programs for young children, in whatever setting, will provide high-quality developmentally appropriate care and education, and, furthermore, that early childhood professionals be well-paid, knowledgeable individuals who demonstrate high-quality performance that results in better educational foundations and quality of life for all of Oklahoma's children. (unpublished)

In 1993, Governor David Walters issued an executive order supporting the efforts and vision of the professional development team. With this support from the Office of the Governor, Ball was hired as coordinator of the Early Childhood Professional Development Team in the summer of 1994. An agreement was made with the University of Oklahoma, College of Education to house the coordinator who worked in partnership with an early childhood faculty member, Loraine Dunn. Dunn created a comprehensive training survey for

child caregivers to collect information on training backgrounds, existing training, and unmet needs and partnered with Deborah Norris from Oklahoma State University to conduct research on the impact of the professional development work. Their work found increases in the quality of care in licensed child care centers in the state, as discussed later in this entry.

Funding from the federal CCDBG was used to move the initiative forward. In an effort to remain inclusive and transparent, the coordinator and professional development team met quarterly and held annual retreats in a geographically central location. It was critical to obtain input from the larger early care and education communities; therefore, working committees were representative of staff and directors of child care centers and family child care homes, regional Head Start, Tribal Child Care and Head Start, community colleges, 4-year colleges, universities, career technology centers, school-age care, and private and public schools. Focus groups were held and sessions were facilitated at state and local professional child care and family child care home conferences. As many as 100 individuals participated on the working committees to involve all sectors of early care and education.

Training consultants were hired for a 2-year period in four corners of the state to train and support staff in child care centers and family child care homes and to make efforts to integrate Head Start training with child care training. In addition, two school-age consultants were hired to work on issues related to school-age care, one covering the western half of the state and the other the eastern half.

Early care and education initiatives during the 1990s focused on four areas: (1) compensation, (2) documenting individuals' professional development, (3) preservice training, and (4) articulation.

1. *Compensation.* A brochure was created to inform legislators, parents, and those in power positions about the salary of child care staff. Oklahoma also participated in a national study on funding for early childhood education led by

Louise Stoney, a consultant specializing in early care and education finance and policy. The state also implemented a scholarship model based on the model of the North Carolina Teacher Education and Compensation Helps (T.E.A.C.H.) Early Childhood Project and created a compensation system called REWARD, which provides incentives for teachers in child care centers and homes to obtain additional education and be rewarded for their efforts.

2. *Professional Development Record.* The state of Washington provided a model based on criteria of the national CDA credential to document the training and education of individuals. The model was retrofitted to Oklahoma's needs. Funding was obtained from a NAEYC Membership Action Grant to provide every staff member in Oklahoma DHS-licensed facilities a copy of the professional development record form. Education was provided for staff on how to complete the record and early childhood professional conferences were organized to solicit sessions that would fit criteria on the grid.

3. *Preservice Training.* Criteria for sessions at state early childhood professional conferences were established based on the CDA competencies. Committees were created to approve topics and qualified trainers using guidelines from the early Child Care Careers, Inc. program. Modules for educating trainers to utilize appropriate teaching strategies for adult learners were developed.

The Entry Level Child Care Training Committee (ELCCT) was formed. OKDHS licensing rules required that 20 hours of entry-level training be completed within the first year of employment in a licensed early childhood setting. It now requires this training to be completed within the first 90 days of employment. Entry level training tailored for family child care home providers and directors is available in-person or online.

In 1997, work began on the OK Training Approval System, OK Early Care and Education Recognition System, the Early Care and Education Career Pyramid, planning for the OK Director's Credential, and the "I Am Your Child" campaign.

The Career Pyramid provides guidance to individuals who teach young children or are considering entering the field of early care and education and serves as a model for other states. The pyramid illustrates professional work opportunities available at the completion of each level of education. The Trainer Approval System provided guidelines for those who want to become trainers and has now become part of the Oklahoma Professional Development Registry. To be approved, individuals must complete a series of modules that support appropriate adult learning strategies.

4. *Articulation.* The first meeting to bring together child development faculty from career technology centers, community colleges, 4-year colleges, and universities was held to explore similarities in coursework syllabi and textbooks utilized in child development and early education class.

A second symposium on articulation was held at Rose State College, and staff of the Oklahoma State Regents for Higher Education guided conversations regarding articulation and credit for prior learning. Early childhood faculty and administrators from all postsecondary institutions were engaged in the process that would provide for students to make easier transitions from one institution of higher learning to another. For example, students who earned an associate degree in early childhood education at a community college would have necessary information and transfer credits to begin a bachelor's degree at a 4-year college or university.

Institutional Change

In 1998 the Center for Early Childhood Professional Development (CECPD) was created using federal CCDBG funds which were funneled through the OKDHS Licensing Services to carry on child care quality work. Charlotte Hollarn was the first director of CECPD followed by Susan Kimmel. The purpose of CECPD was to bring together many child care services that had been housed at other sites. CECPD became the home for Oklahoma Training for Child Care Careers,

video lending library, scholarships for education, and a news magazine for providers.

In 1999, CCBDG funding, provided through OKDHS Licensing Services, was used to form the Oklahoma Child Care Resource and Referral Association, which expanded and coordinated statewide service delivery and uniform data collection to achieve a quality child care system for all Oklahoma families through community-based resource and referral services. In the same year, support from Wheelock College gave impetus to the "Taking the Lead" project, which created a credential program for child care directors providing levels of achievement at the bronze, silver, and gold tiers for directors who work in licensed child care settings. In 2000, school-age programming was added as well as director training and training for CDA advisers who observe CDA candidates and assess their teaching performance.

Oklahoma's QRIS, the Reaching for the Stars initiative, is a tiered system where the lowest star rating signifies that a program meets minimum licensing standards, and higher ratings indicate that a program meets these licensing standards as well as additional quality criteria. The goal was to improve the quality of early care and education programs attended by the highest risk children. Judy Collins and Nancy vonBargen, officials with the state Office of Child Care, were instrumental in strengthening licensing regulations. Under Reaching for the Stars, in order to receive a two-star rating and higher levels of reimbursement, as of 2015, child care programs had to have a certain number of master teachers with an early childhood credential or a college degree with credits in child development, early childhood education, or the equivalent. The increase in education requirements for staff has resulted in improvements in early care and education programs in terms of positive teacher-child interactions.

Oklahoma's professional development initiative included implementing continuing education units (CEUs) for training so that individuals could record their training for use toward receiving or renewing a credential, and encouraging credit for prior learning at postsecondary institutions. The

state also consolidated scholarship awards at the Oklahoma State Regents of Higher Education Office in 2004 and began the Scholars in Excellence program, which provides Scholar Coordinators at every community college with an early childhood program to recruit and support individuals who work with young children and encourage them to obtain an associate degree. This initiative also provides scholarships and support for obtaining the CDA credential.

In 2005, the state's Early Education Professional Development Council voted to develop a single curriculum for the CDA to ensure statewide consistency and accountability and for scholarship purposes. In 2013, this curriculum was revised to meet new CDA 2.0 requirements and to include requirements for another national credential, the Certified Childcare Professional (CCP). Community colleges continue to become accredited through the National Association for the Education of Young Children (NAEYC) Associate Degree Accreditation Program, whose criteria support articulation of child development coursework.

Ball authored, received, and directed two grants intended to support child care staff and directors to obtain training to improve child care quality and strengthen partnerships. One grant from the Head Start Collaboration Project in 2003 called Partners in Change brought an opportunity to provide professional development for regional Head Start and Tribal Head Start and Child Care. The second grant (1999–2001) was an apprenticeship project with funding that was received from the U.S. Department of Labor to support teachers in child care facilities to obtain a CDA national credential.

As the quality assurance initiatives continued, the early childhood field in Oklahoma moved toward acceptance of higher levels of professional development requirements in licensing regulations: a professional development registry for child care staff and directors, approved training based on national CDA criteria, the Stars system for recognizing centers and homes, and environment rating scales (ERS) assessments.

A professional development subcommittee of the Oklahoma Partnership for School Readiness (OPSR) was appointed to coordinate the professional

development for the early childhood system in Oklahoma. OPSR focuses on strengthening families and school readiness for all children. OKDHS Licensing Services brought together individuals to focus on professional development as it impacts licensing requirements for staff.

As of 2015, the Reaching for the Stars system in Oklahoma had four levels for child care programs: one star, one star plus, two stars, and three stars. At that time, it had plans to introduce changes to the system that included requiring all one-star licensed child care centers to have staff become part of the Oklahoma Professional Development Registry and develop a professional development plan. These requirements are intended to increase the quality of existing one-star centers, particularly in relation to family engagement, professional development, and qualifications for master teachers. Funding availability continues to cause changes in the services that are provided to maintain and enhance quality in all Oklahoma early childhood settings. Collaborations continue with the State Department of Health through a “warm line” with child care consultants to answer questions related to children's behavior in the classroom and for making appropriate referrals for additional services for individual children.

QRIS advocates continue with initiatives to professionalize early care and education programs. At the 2015 QRIS National Learning Network, early childhood advocates and policy experts shared information about reducing the fragmentation in early education through establishment of a common universal purpose, a defined body of knowledge and practice, a collective professional identity, and accountability. Advocates for QRISs in Oklahoma made early contributions to this understanding through their strong collaborations and commitment to quality care and education for all young children.

Outcomes

Phase I of a longitudinal study by the Early Childhood Collaborative of Oklahoma found that the quality of care for all Oklahoma preschool children in licensed centers was higher in 2002

than it was in 1999. Higher quality was evidenced through

- sensitive interaction of caregivers,
- increased star levels at substantial numbers of centers,
- decrease in staff turnover rates, and
- better care for children receiving state subsidies.

Unfortunately, planned later stages of research on the Oklahoma QRIS system had not occurred as of 2015. A lack of funding has prevented additional studies from being completed.

R

READ-ALOUDS

Read-aloud is a term used to describe the process of sharing books by reading them out loud so others can take part in the story experience. In general, the term refers to a method through which parents, teachers, and other more experienced readers share stories with children. Read-alouds play a crucial role in the language and literacy development of children and can strongly impact the academic success of young readers. This entry provides information related to the rationale for using read-alouds, the benefits of read-alouds, and recommended guidelines for conducting read-alouds with children.

Rationale for Using Read-Alouds

Read-alouds provide an avenue through which even the youngest children can access and enjoy literature. As caring adults share books with children, they convey their own enthusiasm for reading, sending the message that literacy transactions are a priority and worthy of dedicated time within the daily routine. Early read-alouds frequently serve as children's first opportunity to explore books with varied print and visual texts, offering them an entryway into the worlds of both literature and art.

Home read-alouds often take the form of bedtime stories or occur within the context of a "lap

reading" setting. These informal readings tend to be more interactive than performative, modeling the concept that literacy is social in nature. With planning, teachers and caregivers can provide similarly supportive settings for read-alouds within the classroom. When reading occurs in these types of warm, supportive environments, children are more likely to see reading as a social, joyful experience, which sets the foundation for a positive approach to literacy learning throughout the years.

Read-alouds can serve as excellent models for how one might engage with texts. As adults share favorite stories with children, they provide models for ways in which print and visual story lines can be interpreted and expressed to others. They provide a scaffolded experience that supports emerging readers as they learn to construct meaning from texts. These factors, along with the sheer accessibility and relative ease of implementing read-alouds, contribute to making them a significant educational strategy that can be used across age groups and in varied settings.

Benefits of Read-Alouds

Read-alouds offer myriad benefits and are associated with numerous affective and academic gains. Not only do positive read-aloud experiences usher children into the joy of reading; they also help children to learn a number of basic skills associated with early literacy learning. As children take part in read-aloud experiences, they learn concrete

book handling skills and the basics of how books work. Children who regularly take part in read-alouds begin to internalize story structure, making it easier for them to understand basic literary components and to anticipate characteristics of the beginning, middle, and end of stories.

Research indicates that regular exposure to read-alouds has an impact on children's ability to differentiate between oral and written language structures. Participation in read-aloud experiences is also shown to have a positive effect on children's listening skills and contributes to the development of enhanced comprehension and expanded vocabulary knowledge. As children look closely at a text and hear the corresponding story read aloud, they develop a greater awareness of print and are supported in their emergent literacy development. Adult readers can provide children with high-quality models for fluent, expressive oral reading and can demonstrate effective ways of navigating different concepts of print. Read-alouds provide a venue through which children can learn about more complex concepts and comprehend more sophisticated story lines than they might be able to navigate through their own independent reading.

Recommended Practices

The quality of the read-aloud experience is impacted by a number of factors including text selection, prosody, and opportunities for reader interaction. In terms of text selection, books should be chosen that are developmentally appropriate for the audience and that are characterized by high-quality print and visual texts. The careful selection of a text allows for the read-aloud to contribute to meeting specific goals that might range from the introduction of a concept, curricular enhancement, exposure to a literary genre, identification with a particular character or story line, or the sheer enjoyment of the story.

Prosody, which embodies the intonation, expression, pitch, and pacing that characterizes the act of reading aloud, strongly impacts listeners' ability to both comprehend and enjoy the story experience. Readers can enhance their presentation through

the incorporation of a dramatic element or animated tone, the use of different character voices and sound effects, and by appropriately changing the volume or pace of the reading to enhance the meaning or emotional pull of the story.

Research indicates that children benefit the most from read-alouds that are interactive and invite their participation before, during, and after the reading of the story. Readers can involve listeners by setting a purpose for listening, inviting predictions about what will happen next, encouraging observations, and asking engaging questions. Readers can also involve listeners by inviting them to join in repeated refrains or to take turns reading different parts of the story.

Significantly, read-alouds provide a time for children and adults to bond emotionally, as they engage in quality discussions about a story. These discussions not only support the development of expressive language skills, but also provide the opportunity to make important connections between literary and life experiences.

READINESS ASSESSMENTS

School readiness has been defined by the Gesell Institute of Child Development as a set of skills and behaviors that allow a child to cope and learn in a school environment, physically, socially, and emotionally as well as intellectually, without undue stress. So what does school readiness look like and how is readiness assessed in children who are about to enter school or preschool?

The concept of school readiness was first popularized by the maturationists in the early part of the 20th century. Maturationists proposed that while all children pass through the same stages and sequence of development, each child has his or her own pace and rate of development. This rate or pace of development was influenced by heredity, temperament, culture, health, intelligence, and environment—and by birth date. *School Readiness* by Francis Ilg and Louise Bates Ames was first published in 1964 and updated in 1965 and 1972. The Gesell Institute of Child Development published one of the most popular kindergarten readiness assessments on the market during the 1960s and 1970s. A wide variety of commercial readiness assessments can be purchased today, and schools and districts develop their own measures, as well.

In 1993, the National Education Goals Panel proclaimed that all children should come to school ready to learn. The reality is *all* children *are* ready to learn, but the question remains, *what* things are they ready to learn. All public schools are bound by law to meet the learning needs of each child who, by legal age, walks, crawls, or is strolled through the door on Day 1 of the new school year regardless of readiness or birthday or disability. The passage of the No Child Left Behind Act in 2001 brought greater accountability to schools and increased testing at all grade levels, including the early years, to show adequate yearly progress. The Common Core State Standards, released in 2010 and adopted in 45 states by 2012, outlined exactly what each child has to know and be able to do at each grade level K–12 in literacy and mathematics. As a result of these three events,

school officials are more stalwart than ever that children need to be “ready” at all levels—ready for pre-K, ready for K, and ready for Grade 1. They are even talking about being ready for college in elementary school! But coming to school ready is the most important step because school success has a domino effect through the years.

It can be difficult to understand readiness and how to assess it in today’s young children, however, even though most schools are giving readiness assessments and there are plenty to choose from in the commercial market. There are many definitions, conceptual characteristics, and reasons to use school readiness assessments. Some believe readiness assessments measure a set of academic skills that a child must master, some believe a readiness assessment reveals where the child is on the path of development and informs the teacher as to what the child needs to learn next, some use a readiness assessment as a gatekeeper for those who will be or will not be admitted into a certain program, and still others believe that readiness assessment reveals what the teacher or program did or did not teach adequately.

According to Kelly L. Maxwell and Richard M. Clifford, one readiness assessment cannot be used for multiple purposes. Therefore, schools, programs, districts, and states must clearly define what they see as the characteristics of readiness, purpose for readiness assessments, and how the assessment(s) will be used and administered. Readiness assessments should be part of a complete assessment system. Designing an assessment system ensures that children are not overassessed and that multiple assessments working in synchrony meet the needs of the school.

The most important reason to use a readiness assessment (or any assessment) is to ultimately help the teacher help the child. Here are recommendations, based on expert consensus, for selecting or creating a readiness assessment for young children:

1. Purpose of the assessment must be clear.
2. Matches the program’s or teacher’s definition of readiness.

3. Assesses the whole child: social, emotional, physical, and cognitive.
4. Based on the principles of child development.
5. Recognizes the fact that there is a “normal” range of time for skills to develop rather than being a yes/no checklist of skills.
6. Recognizes that family background, ethnicity, and gender are related to readiness.
7. Possesses the technical properties that meet the program’s or teacher’s needs.
8. Identifies strengths and weaknesses of the child.
9. Results can be communicated with parents in a meaningful way.
10. Easily administered and scored without stress to teacher and child.

the kindergarten to twelfth-grade educational process. By the time children enter the formal K–12 schooling process, there exist wide differences in the development of a variety of skills and understandings related to acquiring the ability to read. The most obvious of these various markers seems to be letter-name knowledge.

At kindergarten entry most students already know the names of most of the letters of the English alphabet (Pearson & Hiebert, 2010, p. 291; Piasta, Petscher, & Justice, 2012). But letter-name knowledge should be thought of as an indicator of much more than simply letter-name knowledge. What letter-name knowledge typically also reveals is that children develop that knowledge in literate home and preschool environments and that letter-name knowledge falls at the end of a long continuum of skills and understandings young children acquire about reading and about print. Yet in many preschool and primary grade classrooms, instruction shares few features with the experiences that lead some children to the knowledge of letter names before they begin formal schooling. This entry discusses what research has found about effective reading instruction, including access to books children want to read, and instruction by high-quality teachers who are supported by professional development.

What young children might know about print and about reading goes well beyond their knowledge of the names of the letters. Children who have experienced a richly literate life prior to entering kindergarten also can identify the front of a book, the first word in a book, and in many instances, they can even identify the first letter in the first word found in a book. These children can also identify the first sound they hear in a word and identify whether two different words rhyme with each other.

It is the children who arrive at kindergarten having already developed these various print, book, and story concepts that typically thrive at school and have little difficulty learning to read. On the other hand, when children have failed to participate in rich literacy events at home and in preschool programs, and have, thus, failed to

READING

Children begin acquiring understandings concerning reading well before they enter school and begin

develop this range of skills and understandings before they arrive at school, these children far too often struggle with acquiring reading and writing proficiencies. Frank Vellutino and his colleagues in 2007 suggested most young children at risk of reading failure have simply experienced “deficiencies in the quality and/or quantity of early literacy experiences” (p. 190). Some children experienced these deficiencies in their homes, some in their preschool and kindergarten classrooms, and some in both.

It is possible to develop some of the markers of early literacy development, such as knowledge of letter names or phonemic segmentation (the ability to distinguish individual phonemes in words), through very focused skill and drill activities. However, multiple studies have indicated that it is only when such lessons are also accompanied by rich language and literature experiences that early reading development is assured.

In fact, as Donald Hammill reported in 2004, three separate meta-analyses involving some 450 studies of the relationship between various specific abilities to later reading achievement indicated that measures of print conventions, letter-name knowledge, and written language were the most accurate and reliable predictors of later reading achievement. Other variables (e.g., phonological skills, intelligence, memory) were less reliable and less accurate predictors, though more often assessed in young children.

Given all the print and story conventions that children acquire when they are read stories and engaged in invented writing activities, and the importance of these understandings in the later development of reading proficiencies, preschool and primary grade classrooms benefit the most children when skills work is balanced by substantial emphasis on meaning and making sense of stories. The creation of “big books” that teachers of young children can use in read-aloud events makes it far easier today not only to read a story to children but also to expose them to the printed story. Teachers of young children just beginning their journey to becoming readers need to make extensive use of such big books. In fact, use of both

big books and traditional books are key aspects of effective early literacy instruction.

Differences in Print Environment

In 2002, Anne McGill-Franzen, Cynthia Lanford, and Ellen Adams reported substantial differences in the print environments between publicly funded preschools and other preschools serving children from low-income families. These differences ranged from enormous differences in the number of books available in the libraries that were located in the preschool classrooms to differences in the number of story read-alouds, and the number of opportunities for children to engage in writing or invented writing. In each case, it was children attending publicly funded preschool programs that were shortchanged. It seemed not to be a lack of funding that explained these differences but, instead, a different model of instruction that led to these differences. These various differences in program design and materials led to quite different outcomes, with children from low-income families enrolled in publicly funded preschools again failing to develop the literacy proficiencies that were observed in the low-income children attending the privately funded preschool programs.

This observed shortage of books extends upward into elementary schools serving primarily children from low-income families. As with preschools, a lack of funding seems not to be an explanation for the more restricted access children from low-income families have to books in both classroom and school libraries. Nonetheless, children from low-income families have fewer books in their homes, their neighborhoods, their classrooms, and their schools when compared with children from middle- and upper-income families. Too often, poor children reside and attend school in “book deserts.”

This general absence of books from schools attended primarily by children from low-income families as well as substantially restricted access to books in environments where these children live appears most strikingly during the summer months when children no longer attend school. We know

that children from low-income families are far less likely to read voluntarily during the summer months than are children from middle-income families. And as a result of a large-scale study conducted by Richard Allington and his colleagues (2010), we also know that providing children from low-income families with books during the summer months, books these children have selected themselves, largely eliminates summer reading loss typically experienced by children from low-income families.

Access to books that a student wants to read and books the student actually can read seems routinely superior for children from middle-income families when compared with the access that children from low-income families experience. Volume of voluntary reading is also established as a causal factor in reading development, and voluntary reading volume is linked to access to appropriate books. Yet for whatever reasons, children from low-income families have been found to read less both in school and out of school than do their more economically advantaged peers. In addition, as Barbara Foorman and her colleagues (2006) have demonstrated, time spent engaged in reading during reading lessons predicts reading growth across the school year. That is, reading lessons that feature much engaged reading by students produce greater reading growth than lessons that feature less engaged reading.

Use of Commercial Core Programs

Research has also indicated that the use of any commercial core program is an unlikely path to effective reading instruction. Peter Dewitz, Jennifer Jones, and Susan Leahy (2009) analyzed the five major commercial core reading programs. Their analysis examined the adequacy of the reading comprehension lessons provided by each program. They reported that none of these core reading programs actually offered any comprehension instruction that matched any findings in the research. They noted that too often only a week was scheduled to develop important comprehension processes, and guided practice of the

comprehension skill to be developed was lacking, as was the gradual release of responsibility. Finally, Dewitz and colleagues reported that guidelines for discussion are almost absent from these programs even though research has demonstrated the power of student discussion on reading comprehension development. Dewitz and colleagues argue that faithfully following any flawed commercial core reading program is not a recipe for improving reading development.

The limitations of commercial core reading programs were also noted in a 2006 study by McGill-Franzen and colleagues. They reported that over 25% of all third graders in the state of Florida failed to achieve the necessary reading performance to be promoted to the next grade. In other words, they argue, none of the core reading programs provided teachers and their struggling reader students with any useful support. Given the national performance record in reading achievement in high-poverty schools, it would seem that the instruction provided in core reading programs fails to meet the needs of many children.

High-Quality Literacy Instruction

What aspect of reading instruction assures that most students will develop as effective readers? The answer seems to be enrolling in the classroom of a high-quality teacher. The evidence also suggests that when schools provide classroom teachers with effective professional development, reading difficulties among students decline.

In a 2008 study by Donna Scanlon and colleagues, children in first grade were enrolled in classrooms under three different conditions—teacher professional development in the interactive strategies approach to literacy instruction, supplemental intervention services for struggling readers, or both professional development and the availability of supplemental reading intervention services. They found all three options reduced the number of children who struggled while learning to read. However, providing classroom teachers with effective professional development on enhancing the quality of their reading lessons reduced reading

difficulties to the greatest extent. In other words, too many primary grade teachers lacked the expertise needed to intervene effectively when children had difficulty. The professional development provided in this study developed that expertise.

In a 1999 study by McGill-Franzen and colleagues, professional development was provided for a sample of urban kindergarten teachers while another sample of urban kindergarten teachers served as the control group and did not participate in professional development offerings. At the end of the kindergarten year, there were clear differences in the reading achievement outcomes for children in these two types of classrooms. Most significantly, the early reading development of the urban kindergarteners enrolled in the classrooms of teachers who participated in the professional development program was accelerated into the average achievement range, while the children in the control classrooms performed well below the average achievement range. Other researchers have also found positive effects of professional development on student reading achievement.

The research suggests, then, that developing expertise of classroom teachers concerning children's early reading development leads to reading instruction that better meets the needs of at-risk students. That said, few school districts or states seem to have focused on providing such professional development activities.

Conclusion

We know more about the nature of effective reading instruction than one might expect if one simply observed reading lessons in American schools. Access to books that a child can read and books that the child wants to read is an important aspect of effective reading instruction. Yet, in American schools such access is more often the case in schools serving few children from low-income families. Access to effective literacy lessons is also an important factor and yet good analyses demonstrate that the most commonly selected instructional support—commercial core reading programs—fails to provide classroom teachers

with effective models for literacy lessons. Finally, we know how to develop the expertise of classroom teachers so that virtually all children who enter kindergarten will be reading on grade level by the end of first grade. But again, few state education agencies or school districts provide such professional development for teachers.

We can do better, particularly for the futures of children from low-income families; we must do better in crafting effective instruction that develops all children as effective readers and writers.

REASONING AND PROBLEM SOLVING

Early childhood education has changed rapidly in recent years as a result of the significant increase in knowledge about how young children learn. As a result, early childhood educators are now focusing to a greater degree on experiences that develop reasoning and problem solving. Reasoning and problem-solving skills are the foundation of the learning process and need to be integrated in every area of child development. Problem solving requires that children take the knowledge and experiences that they have, in order to be able to learn what they don't know. It also includes overcoming difficulties and presenting suggestions and trying them out. Reasoning is the cog of problem solving, which involves the capacity to think through problems and apply different approaches for solving them. This entry discusses learning experiences that help to develop problem solving and reasoning in young children and how activities that integrate science, technology, engineering, and mathematics (STEM) in particular can help develop problem solving and reasoning.

Although typically problem solving and reasoning are framed into specific school disciplines, they both need to be part of any developmental and curriculum area. They should be found not only in core academic areas like science or math, but in socioemotional, language, physical, and cognitive development areas as well. A child who is exposed to an array of opportunities to apply problem solving and reasoning skills is more likely to become competent in understanding real life problems, determining what needs to be done, finding a strategy, planning accordingly, and checking to see if it works. These fundamental abilities create the groundwork for success not only in academic and social areas, but in life.

Problem solving and reasoning are skills that can be learned, and it is critical to develop those skills in the early years. Adults and teachers around children in their first eight years of life need to understand that they have to intentionally design learning experiences that support and promote the progress

of problem solving and reasoning. Children need to be exposed to different situations, materials, and experiences for them to be able to develop those skills. Through that process they will recognize, understand, and analyze a situation. They will be making choices and decisions and learning core knowledge. The students could be working to solve a problem individually or collaboratively. If they work in groups, they will also learn to communicate effectively and to validate different points of view. Play episodes are an ideal scenario for that.

Play is considered the universal language of childhood and the most effective means by which children understand each other and the world around them. It also has a vital role in an early childhood setting by enhancing reasoning and problem-solving skills. Through play, children practice what they have learned and also create new knowledge. They develop cognitively and socioemotionally while playing by themselves or with others, solving problems in the process. Constructivism is creating new knowledge by problem solving and reasoning and is intrinsically attached to play in the early years.

Developmental Stages of Problem Solving and Reasoning

Children begin to acquire problem-solving and reasoning skills early in life. The problem-solving and reasoning process begins from the moment an infant develops muscle control and hand-eye coordination. The infant will use his or her senses to explore the world and to start understanding cause and effect relationships. During the first two years, activities in which the infant and toddler can expect a reaction from an action should be encouraged. For example, toys in which the child pushes a button and something jumps out of the box, or a song starts to play, teach prediction, observation, and cause and effect.

By 3 years old children can start applying problem-solving and reasoning skills to more specific situations. The use of open-ended questions is necessary in this stage. An adult can say, "It is very cold. We can't go outside. What could we do

instead?" The children would be able to think about the problem, reason about what to do, use previous information, and then find a solution.

Older children can engage in a more scientific method to solve a problem. Between 3 and 5 years old, reasoning develops considerably. It is clear how significant it is when instead of assuming a passive role, preschool children assume an active one by engaging in generating a hypothesis, gathering data, predicting what will happen, and observing the results. They are prepared to work in groups and use verbal cues to negotiate.

By the time they enter elementary school, students start to think more abstractly. That means that they can think about a problem and imagine the solution without having to engage necessarily in a trial and error concrete activity. Around 8 years old, the problem-solving and reasoning process will be nearly developed contingent on the experiences to which the student was previously exposed.

Problem Solving and Reasoning Through STEM

One way to begin incorporating problem-solving and reasoning skills in the preschool years is through STEM activities. STEM can be defined as an approach that integrates the content and skills of science, technology, engineering, and mathematics. Through STEM children are encouraged to solve real problems through specific steps. These steps are designed to allow them to take control of their actions and apply what they have learned to solve a problem. Those steps also focus on the collaborative aspect, which allows children to interact and to see different perspectives. Based on the recent and growing research in early brain development, it becomes clear that preschool age provides the best moment to start focusing on STEM, in order to expose children to specific and concrete activities of problem solving and reasoning.

Conclusion

It is important to remember that problem-solving and reasoning skills are not isolated activities. They

need to be taught in a holistic way and as part of every aspect of a child's development. Younger children have to be exposed to experiences that allow them to create the foundation to learn the basic strategies to solve problems. Problem solving and reasoning are part of a mind-set that empowers children to think logically, critically, and ultimately, as they solve real world problems, to be active members of their community and society.

RECESS

Recess refers to a break from work of some type. In the adult world, a break taken by courts and legislatures is called recess. School recess is a scheduled break in the structured work of the school day when children, supervised by teachers or playground supervisors, can play with their classmates and choose their own activities.

Recess is generally held outdoors; however, during inclement weather, recess can also be held

indoors, either in the school gym, where children can play active games, or in the classroom, where children are allowed to choose from more quiet activities. Preschool children have time designated for outdoor play, but it is generally referred to as outdoor playtime rather than recess, perhaps because the rest of the day for the preschool child is not thought of as work. In the United Kingdom, recess is called *breaktime*. Typical activities during recess include climbing, sliding, running, swinging, talking with friends, jumping rope, playing ball games, playing clapping games, telling jokes, chasing, pretending, digging, and organizing games. While engaged in these activities, children lead, follow, organize, and resolve conflicts.

History of Recess in the United States

According to recess researcher Anthony Pellegrini, the origins of recess in the United States are unknown. Pellegrini notes that some early schools were built without playgrounds, which may or may not mean they had no outdoor break in the day. The ability to play without a playground was illustrated by American artist Winslow Homer, who painted an 1872 picture of boys playing “snap the whip” outside their one-room school and an 1873 picture of a boy being deprived of noon recess as punishment while other children run around outside the window. These images suggest that recess was common, at least in rural areas. In the early 1900s, the child study movement, influenced by the father of American psychology G. Stanley Hall, promoted an appreciation for the value of play and encouraged recess as a time when children could choose what they wanted to do.

Children born during the first eight decades of the 20th century likely had daily recess, often during the morning and again in the afternoon. However, *A Nation at Risk*, a 1983 document that decried the mediocrity of the American education system, was soon to increase standardized testing and discourage play as frivolous. In 1989, a survey conducted by the National Association of Elementary School Principals (NAESP) found that 90% of the nation's school districts reported at

least one recess period daily. But, soon after the NAESP survey was completed, schools began to decrease or even eliminate recess to allow more time for academic subjects.

This trend was exacerbated by the No Child Left Behind (NCLB) Act of 2001 with its focus on high stakes testing in literacy and mathematics. According to a 2008 report from the Center on Education Policy, 20% of school systems decreased recess time after NCLB, averaging cuts of 50 minutes per week. In 2011, Kathleen Burris and Larry Burris determined that 5.3% of randomly selected school systems reported increases in recess while 32.3% reported decreases.

Whether or not a child has recess seems to be a social justice issue. Although cutting back on recess may be intended to provide more instructional time, thereby closing the achievement gap between middle-income children and children in poverty, many poor children miss opportunities to engage in physical activity, practice social skills, and have needed mental breaks. In 2002, Jodie Roth and colleagues studied a randomly selected sample of children on a randomly selected school day and found that 79% of the children had recess. However, 85% of White students had recess compared with only 61% of the African American students and 75% of other minority students. Socioeconomic differences were also found, with 83% of those living above the poverty line having recess compared with 56% of those living below the poverty line. Opportunity for recess also differed by test scores, with 85% of the children above the mean on standardized tests having recess compared with 75% of those below the mean.

Not only do high-poverty schools schedule less recess, but recess deprivation is also regularly used as punishment, causing some of the most vulnerable students, especially boys, to regularly lose recess. Abolishing recess and focusing only on academics has not narrowed the achievement gap and may make classroom management more difficult. It may also have led to increased diagnoses of attention-deficit/hyperactivity disorder among children who need more physical activity than the school provides.

Policies and practices governing physical activity vary from state to state and school to school. The National Association of Sports and Physical Education recommends that elementary school students have at least 150 minutes of physical education (PE) per week and 20 minutes of recess a day. However, only a handful of states specifically require recess. According to the National Association of State Boards of Education, the recess requirements in Missouri and Hawaii specify that it should last at least 20 minutes per day, while Virginia allows the timing to be determined by the school. According to Sandy Slater and colleagues, the probability of public school third graders having 150 minutes of PE per week and 20 minutes of recess a day is greater in states with laws requiring PE and encouraging recess.

Recess in Various Countries

In many countries children have more recess than U.S. children have. For example, students in the United Kingdom have breaktime in the morning and afternoon and long lunch periods that allow time and space for play. Many Japanese children have 10 to 20 minute breaks between 45 minute lessons or 5 minute breaks between lessons and a long lunch. Finnish and Turkish students have 15 minute breaks after each 45 minutes of work. In Uganda, the school day is long, generally from 9 a.m. to 5 p.m. However, the children have a 30-minute play break in the morning and one hour for lunch and play. Then from 3:30 to 5:00, they have a choice of fun activities such as sports, clubs, art, and music.

Research Conducted During Recess

There are three major types of research conducted during recess: (1) comparisons of activity level during recess and at other times during the day, (2) analyses of gender differences on the playground, and (3) research on types of play and other behaviors occurring during recess on various types of playgrounds. Olga S. Jarrett provided references for many of these studies in her 2013

white paper on research supporting the need for recess. Several studies using pedometers, accelerometers, or heart rate monitors have found that children are more active during recess than during PE classes or after school. Experimental research has also found that when children are inactive in school, they are also less active after school, indicating that they do not compensate for their sedentary school behavior with increased activity when they have more free choice.

Research on gender has consistently found that boys and girls tend to self-segregate during recess. Boys are more active than girls and tend to play more games in larger groups, including ball games such as soccer, handball, and basketball if facilities are available. Girls' activities during recess are more verbal in nature including clapping games, jump rope rhymes, and pretend play. According to Pellegrini, gender segregation begins around the age of 3 and lasts until age 8 to 11. The types of play during recess depend on the length of recess as well as the playground equipment and moveable parts (such as hula hoops, balls, jump ropes, and moveable junk materials) available. Research reported by Joe Frost and colleagues suggests that traditional playground equipment promotes primarily exercise play, while loose parts, sand, nature areas, and open spaces promote more social interactions. Expensive playground equipment might be nice but is not necessary for a good recess experience. Anna Beresin and service-learning students from her university distributed balls, hoops, jump ropes, and chalk to high-poverty urban schools where playground equipment was not available. They found that even these inexpensive items promoted positive, active play during recess.

Benefits of Recess

Recess has many academic, physical, and social-emotional benefits for children. In a 2010 report, the Centers for Disease Control and Prevention summarized the eight recess studies that examined effects of recess on some aspect of academic performance, such as attention or

on-task behavior, and concluded that each of these studies showed at least one positive relationship between having recess and improved academic behavior (e.g., greater attention, less fidgetiness, and more on-task behavior) after recess. These findings can be interpreted through brain research that concludes the brain needs breaks to recycle chemicals and that exercise improves mental concentration. When recess improves classroom behavior, the teacher also benefits.

Recess is the time in the day when children are likely to be most active, and the active play that occurs during recess has physical benefits for coordination, increased stamina, and prevention of childhood obesity. As children run, climb, chase, and balance, they develop control of their bodies and challenge themselves physically. Research conducted by Pellegrini found that children are most active when they first arrive at the playground, showing their need to move after a period of being sedentary. Cynthia Ogden and colleagues report that childhood obesity has increased exponentially in recent years, especially among Mexican American and Black children. Although one cannot conclude causality, the ethnic groups with the highest incidence of childhood obesity are also the least likely to have recess, suggesting that they might benefit from more activity.

Recess provides an excellent opportunity for children to learn social skills such as sharing, planning, turn taking, and leading and following. In fact, recess may be the only time in the day when children are free to interact with their peers. Generally children teach one another these skills. They must learn to resolve conflicts to keep the game going, resulting in low levels of conflict on the playground. However, children who have been long deprived of recess may not know how to organize their own games, take turns, or play fair. Some schools have hired an organization called Playworks to provide play leaders to teach games and make sure all children are included during recess. Research has shown that Playworks schools report less bullying and smoother transitions to the classroom. There are physical and social benefits to

introducing new games, making sure that isolated children are included, and teaching conflict resolution skills on the playground. However, if recess intervention programs become too structured, children may not be encouraged to organize their own play and the result is no longer *recess* as defined by the ability to choose one's own activities.

As one of the few times in the school day when one can observe spontaneous peer interaction, teachers who supervise during recess have good opportunities to observe leadership, prosocial behavior, social isolation, and negative social behavior. Seeing how their students interact socially can help teachers and other playground supervisors intervene in situations involving aggression or social isolation.

Supporters of Recess

In 2013, the American Academy of Pediatrics published an important position statement on recess stating "recess is a crucial and necessary component of a child's development and, as such, it should not be withheld for punitive or academic reasons" (Murray & Ramstetter, 2013, p. 183). In addition to the pediatricians and play organizations such as the American Association for the Child's Right to Play (IPA/USA), the Alliance for Childhood, and the US Play Coalition, other supporters of recess include the National Association for Sport and Physical Education, the National Association of Early Childhood Specialists in State Departments of Education, and the National Association of Elementary School Principals.

RECOMMENDED EARLY INTERVENTION PRACTICE GUIDELINES

Early intervention refers to comprehensive developmental and educational services for young, vulnerable children from birth to school entry and their families. It consists of anticipating, identifying, and responding to child and family concerns in order to maximize children's development and learning.

To provide high-quality early intervention services and supports, the Division for Early Childhood (DEC) of the Council for Exceptional Children periodically identifies, validates, and disseminates recommended practice guidelines for the field. DEC is an international membership organization whose members include teachers, therapists, family members, and others who care for, or work on behalf of, young children with special needs and their families. The organization promotes policies and advances evidence-based practices that support families and enhance the optimal development of young children.

The DEC Recommended Practices, published in 2014, have been shown to promote improved development and learning for young children who have or are at risk for developmental delays or disabilities, and to support their families. These practices are intended to guide professional early intervention providers (e.g., teachers, speech-language pathologists, physical therapists, occupational therapists, social workers) and families in the most effective ways to improve outcomes for children birth to 5 years of age. The practices have been shown to result in better outcomes for children and the personnel who serve them. Further, the practices embrace the concept of inclusion by promoting the participation of children and families in natural, inclusive environments in their communities. They also honor the cultural and linguistic diversity of children and families.

The recommended practices are based on the best available empirical research evidence as well as the wisdom and experience of the early intervention field. Because the research evidence is

always changing, DEC labeled the practices *recommended* to convey the sense that effective practitioners are themselves responsible for knowing the research, making informed decisions about use of practices, and assessing the impact of the practice on individual children and families.

These guidelines define practices as observable actions that are known to promote development and learning. Further, these practices are intended for those young children with or at risk for developmental disabilities and/or significant learning challenges. The practices are not specific to any one disability. They are considered essential or high leverage and may be supported by more specific actions or sets of actions for individual children and families. Indeed, individualization is one of the recommended practices. The practices build on but do not duplicate practice guidelines or standards for all young children. Developmentally appropriate practice, an approach to teaching grounded in theory and research on how young children develop and learn, is generally considered the foundational guidance for teaching all young children.

Development of the Practices

The 2014 version of the recommended practices represents the third iteration of guidance for the field. Previous versions appeared in 1993 and 2000. A commission made up of researchers, administrators, practitioners, and family members met to review the existing practices and definitions, and develop a strategy for updating them. Work groups consisting of additional researchers, administrators, practitioners, and family members with specific interest and expertise in a content area met to develop practices for each content area and to nominate published, peer-reviewed evidence to support the practices. The commission reviewed the practices and evidence and made suggested revisions. Following several revisions, experts in the early intervention field reviewed the practices.

Concurrently, a small group of researchers validated the nominated research evidence to determine if the research supported the practice and if the

research was sufficiently rigorous. It put in place a strategy to continually identify research to confirm (or disconfirm) the practices as the research becomes available.

Content Areas

The practices are arranged into eight topics: leadership, assessment, environment, family, instruction, interaction, teaming and collaboration, and transition. Brief descriptions of these topics are as follows:

1. Leadership practices include the practices that help individuals and teams implement the recommended practices within their program, school, agency, or organization.
2. Assessment is the process of gathering information to make decisions. It is conducted for the purposes of screening, determining eligibility, conducting individualized program planning, monitoring child progress, and measuring child outcomes.
3. Environmental practices refer to aspects of space, materials, equipment, routines, and activities that practitioners and family members can alter to support children's development and learning.
4. Family practices are those that support active participation of families in their child's development and learning, as well as achieving the family's own goals. Family practices build on family strengths and support choice and control.
5. Instructional practices are intentional actions that are designed to inform what to teach, when to teach, how to teach, how to evaluate the effect of those practices, and how to support others in using the practices.
6. Interactional practices are those practices that support back and forth exchanges between children and others and are intended to promote children's development and learning. Sensitive, responsive caregiving and teaching are fundamental practices in early intervention programs.
7. Teaming and collaboration refer to practices that enable professionals and family members to work together in ways that support children's development and learning.
8. Transition refers to the events, activities, and processes associated with key changes between environments or programs and the practices that support successful adjustment of the child and family while making these changes.

Historical Context

Congress passed the nation's major special education law, Pub. L. 94-142, now called the Individuals with Disabilities Education Act, in 1975. That law provided for education-related services for school-age children. In 1986, Congress approved Pub. L. 99-457, Education of the Handicapped Amendments, to ensure that infants, toddlers, and preschoolers with developmental delays or disabilities received early intervention, special education, and related services to meet their individual needs. While the federal laws assured access to services, the legislation could not assure their quality. There were no national standards of practice to guide professionals or to inform families about effective services.

DEC recognized that gap and organized a task force in the early 1990s to address the issue. Much research existed and had, in fact, served as the basis for passage of the law. But guidelines for early intervention practice were scattered among various scientific journals and reports. The task force created opportunities for researchers, teacher trainers, teachers, therapists, and family members to serve as members of focus groups and to identify recommended practices based on research and experience. It identified practices that could serve as guidance for the field. The practices were subjected to a field validation, and the resulting 415 practices were disseminated to the field in 1993.

About a decade later and with a renewed emphasis on empirical research evidence, DEC organized another group to review and update

the practices publication. This process involved an extensive review of peer-reviewed, data-based literature, another round of focus groups with researchers and stakeholders, and a synthesis of the literature based on focus group results. Again, the practices were subjected to a field validation. DEC recommended a set of 240 practices and disseminated it to the field in 2000.

Response to both of these earlier versions was positive but the sheer number of practices was overwhelming to many practitioners and families. Therefore, the 2014 version of the recommended practices sought to identify those practices that have the highest expected leverage and impact. The process described resulted in 66 recommended practices. Finally, in recognition that the research evidence grows and changes, the organization established a process to continually identify, validate, and disseminate new practice guidelines based on the research evidence.

REFLECTIVE PRACTICE

Reflective practice is a phrase that, despite being commonly used in a variety of contexts, remains somewhat nebulous in definition, and as a result draws criticism for being both overused and vague. At the most simplistic level, reflective practice might be considered intentional thought about the actions one takes in carrying out the duties of a given profession. However, few educators would agree that all thinking about practice is reflective, nor would there be support for the idea that any action can be justified simply because it was deliberate.

Though reflective practice appears in the literature across professions like nursing and social work, this entry discusses how it is defined within the teaching arena. As such, reflective practice can be defined as instructional practices and related actions that are carried out as a result of intentional questioning and critiquing of beliefs, practices, or knowledge with the intent to become more mindful of and responsive to the associated assumptions, implications, and outcomes associated with learning. In order to better understand this complex concept, it is important to be aware of the origins of reflective practice in education as well as both the processes associated with and the practical applications of such practices.

Historical Roots of Reflective Practice

Reflective practice can be traced to the early-20th-century work of John Dewey, an American philosopher and psychologist whose democratic teachings helped shape public education. He suggested that reflective thinking was actually a better way of thinking and that such thinking involved giving serious consideration to a subject with the goal of achieving a particular purpose beyond that of entertainment. He wrote that without reflective thought, being correct was nothing more than an accident, and that in contrast, reflection led to conclusions that were evidence based. Dewey's work indicates that those who think reflectively

share three characteristics: open-mindedness (the desire to see more than one side and recognize the possible error of our ways), responsibility (the willingness to move beyond whether something works and take into consideration the consequences), and wholeheartedness (the belief that new learning is always possible, accompanied by a commitment to finding possible solutions).

Despite the apparent logic of Dewey's work in this area, reflection was not a major consideration in most teacher education programs nor associated with teaching in general until Donald Schon's work gained traction in the mid-1980s. Schon, an influential thinker in the area of reflective practice and professor at the Massachusetts Institute of Technology (MIT), theorized that professional knowledge can only go so far in that the situations encountered in professional practice are complex, uncertain, and continually evolving. In essence, knowledge alone cannot sustain professionalism since it cannot keep up with the demands of practice. Thus, he argued, reflection must be established as a legitimate form of professional knowledge, further explaining that both reflection-in-action—that which takes place during teaching—and reflection-on-action—that which takes place before or after teaching—are critical to the process of being a reflective practitioner.

Since the time of Dewey and Schon, others have suggested other aspects of reflective practice including reflection-for-action—that which guides future action based on past thoughts and actions, as well as the idea that reflective practice does not have to be solitary—that it can occur as an outgrowth of conversation among professionals. Despite the fact that reflection has been a common part of what is considered good teaching practice for less than half a century, most have come to accept the notion that reflective practice refutes the idea that teachers are unable to generate their own knowledge and are doomed to a professional life in which they simply receive knowledge from other, more learned individuals. Reflection combats the degree to which instructional decisions are made without a conscious and conscientious decision

that they are the most appropriate decisions for the particular context.

Processes Associated With Reflective Practice

Reflection itself is typically triggered when a teacher encounters something confusing or out of the ordinary. In the field of teaching, these experiences do not just happen in response to a particular teaching event or assessment; moments of disequilibrium can be triggered by teaching materials and programs, mandates and directives handed down from above, education policy, or anything that happens within the context of the classroom, school community, or education at large. Such reflection is holistic, involving intuition, emotion, and passion, and is influenced by context and situation. In today's efficiency-oriented society, managing those characteristics can be challenging, but reflective practitioners place a high value on long-term development over immediate proficiency and recognize that efficiency can, in fact, be a direct threat to reflection.

Reflective practitioners do not see themselves as technicians who, when faced with problems, rely on fixed assumptions that often lead to limited outcomes. Rather, they tend to question problems from different perspectives looking for multiple potential solutions. They are able to question institutional and cultural contexts without arrogance and neither blindly reject nor accept what is commonly perceived as truth. They make educated guesses about the problems they encounter in the classroom on a daily basis, particularly when there is a gap between their expectations and the results, and they continue to frame and reframe dilemmas in light of knowledge and experience. Reflective practice involves a continuous and ongoing cycle of taking action, observing, analyzing, and planning—sometimes quickly in the moment, and sometimes in a more systematic approach that looks toward long-term change.

Professionals are typically considered experts in their field of study, and teachers are no different. However, being an expert can simply mean

that one has the knowledge required in order to practice in the field. Reflective practitioners set themselves apart from experts by acknowledging that while they have the relevant knowledge required, they are not the only ones who have relevant knowledge. They don't just use the resources provided to them; they consider how best to use the resources to achieve the instructional goals in the particular context in which they find themselves. They take responsibility for the instructional practices they choose to employ and are active participants in the work of the classroom. Reflective practitioners find ways to be autonomous when it comes to professional decision making.

Practical Applications of Reflective Practice

Because the reflection portion of reflective practice typically takes place inside the mind of the teacher, it is not always easy to identify whether practice is truly reflective or not. However, there are some actions that are more indicative of reflective practice than others. Using assessment to inform instruction, employing small group instruction, and offering differentiated assignments are all examples of teaching practices that typically fall under the purview of reflective practice, because in order to execute them in a meaningful way, reflection-on-action in the form of planning must occur.

Using Assessment to Inform Instruction

Teachers who simply move through a textbook or pacing guide from one lesson to the next without taking into consideration the needs of their students are not engaging in reflective practice. In contrast, teachers who use formative assessment, ranging from observational data to student performance on tests, in order to plan instruction are typically engaging in actions considered to be reflective in nature. In these kinds of classrooms, there is a cyclical and ongoing relationship between effective

assessment and effective instruction in which teachers notice patterns of student performance and aim to provide support where they see gaps.

Small Group Instruction

Whole group instruction remains prevalent in many classrooms, and while employing this approach to instruction does not preclude reflective practices, when teachers use it as the primary means of delivering instructional content they are less likely to be actively engaged in reflection. Classroom instruction in small groups should involve thoughtful construction of the groups. Possibly the grouping strategy that requires the most reflection is called flexible grouping, that which occurs when groups are chosen based on a specific purpose, meet until the specific purpose is accomplished, and are then disbanded in order to form new groups for new purposes. With rare exception, grouping students for instruction cannot be done well without planning. Rather, it should be a deliberate process based on purpose, assessment, and evidence, and membership—even in flexible groups—should be continually monitored and adjusted based on individual performance and growth. These actions are all indicative of reflective practice.

Differentiated Assignments

Offering meaningful options for a variety of ways in which students can demonstrate what they have learned also requires reflective practice. Teachers must ask themselves questions such as “Did any of my students have a hard time relating to the materials or the products they will need to use to express what they know?” or “What other products will demonstrate that they have mastered the material I have taught?” In some instances the answers to the questions might suggest that appropriate differentiation might be as simple as letting a student who struggles with fine motor skills record his or her oral answers to essay questions rather than attempting to write them out by hand. In others, the teacher might decide to provide multiple options for documenting understanding, and leave

the decision for selecting the assignment in the hands of the student. For example, as part of a study on cells, students may choose to create a model that includes accurate representation and labeling of the parts of the cell, to write a report that includes a description of the parts of the cell, or to videotape themselves giving a lecture on the parts of a cell. Each product, though different, would provide the teacher with similar insights regarding the students' understanding of cells. Differentiating assignments effectively, again, requires deliberate thought—intentionally planning with foresight—a hallmark of reflective practice.

In sum, reflective practice involves deliberate consideration of educators' own beliefs and practices, their students' performance, and the relationship between their students' performance and their own beliefs and practices. Educators who employ reflective practices use their knowledge, experience, and values to inform their classroom instruction and assessment; they conduct their own research as they go throughout their days, weeks, months, and years in the profession; and they analyze how their actions influence student learning and growth. Reflective practice requires a conscious and voluntary effort to interrupt the routines of teaching that can become habit, to continually self-assess in an attempt to improve, and to willingly alter beliefs and practices after careful analysis all in order to make learning more effective for students.

REFUGEE CHILDREN

In 2014, the United States admitted 73,000 refugees. According to the 2014 United Nations High Commissioner for Refugees (UNHCR) Global Trends, children below 18 years of age constituted 51% of the refugee population. By the end of 2014, there were almost 60 million refugees and internally displaced people worldwide, according to the UNHCR.

Refugee children arrive in the United States due to war, political uprisings, resettlement, violence, bombings, forced displacement, genocide, loss of parents and family members, loss of homes, and poverty. Unaccompanied minors come to the United States as well. Refugees come for a better life, a future, and survival.

Children bear the vestiges of the traumas and emotional stress of their experiences. They may present with health issues as well. These experiences contribute to risk factors that challenge children's adjustment to life in the United States. Lack of prior formal education, limited or interrupted formal education, lack of proficiency in English, or poorly educated parents may complicate children's adjustment to school. The severity of the traumas experienced by the children may lead to mental health issues. Resources to address these needs are essential to the education of refugee children.

There are immediate challenges in meeting the needs of children who have arrived from countries previously unrepresented in the U.S. refugee population. The need for translators for various language groups is acute. Refugee children who are culturally and linguistically diverse (CLD) require teaching strategies that are responsive to their needs. For the purposes of this entry, culturally and linguistically diverse refugee students are from countries experiencing violence, conflict, and human rights concerns. These students, whose primary language is not mainstream English as spoken and used in U.S. classroom settings, are from different ethnic and racial minority groups as well. English language learner (ELL) services are not sufficient for the needs of all refugee children.

The students are a heterogeneous population. Grade placement of children based on age estimates, rather than grade completion, coupled with a lack of prior formal education or discontinued education pose challenges for students and their teachers. The Division for Early Childhood (DEC) of the Council for Exceptional Children's 2010 position statement, *Responsiveness to All Children, Families, and Professionals: Integrating Cultural and Linguistic Diversity into Policy and Practice*, is an important resource for educators.

For students and their families, learning the nuances of a new culture and understanding social services and education and government systems are challenges. These issues become a concern for children, who often serve as their families' culture guides because children become proficient in English and American customs more quickly than their parents do.

Teachers in early childhood settings must determine if refugee children need special education services. In the case of children who are CLD, assessments in the diverse languages may not exist. Assessments in the languages of the students and specialists who speak the languages and are trained to administer the assessments are needed. The Culturally and Linguistically Appropriate Services (CLAS) website, maintained by the Early Childhood and Parenting Collaborative at the University of Illinois, is a helpful resource.

If a child has special education needs, the process for securing services requires family involvement. The processes are often complex and possibly unknown to the family. Support for the families in this situation is necessary.

There are different points of view on the use of assessments, particularly for early childhood students who are CLD. One approach is to "wait and see" because of a concern about overrepresentation of students who are CLD in special education. The second approach is to identify students who need special education services as early as possible in the child's development since time is a critical factor. An additional challenge is delay in evaluation due to limited staffing and high numbers of students who require evaluations.

In response to these issues, teachers report the use of alternative processes for evaluating student skill levels when formal assessments are not available. Teachers use assessment skills not dependent on language. Although the strategies are not standardized, they provide insight into the child's development. Strategies include observations of students at play and their interactions with other students and conversations with parents (with the assistance of translators) about their children's development and skills.

The strategies used are not new; however, they are targeted specifically to the refugee students. Teaching strategies include the increased use of visuals in conjunction with reading activities. New vocabulary is presented gradually and as simply as possible. Interactive, cooperative group activities and hands-on learning are emphasized. Friendship development and the social dimensions of school are important as well. For children, school is a learning environment and a social environment. An emphasis on culturally responsive practices is essential.

A useful resource in the determination of a child's development is the Protocol for the Routines-Based Interview (RBI) by Robin McWilliam. The structured interview allows families to contribute information about a child's development across developmental domains.

Teachers need professional development opportunities that address the growing diversity of schools and the needs of culturally and linguistically diverse students. The schools need translators and ELL teachers who can meet the needs of the refugee students. Schools are a point of contact with the new culture and schools. Teachers and students have a great impact on the lives of refugee children. Schools provide refugee children with opportunities for social interactions and friendships as well as acceptance.

Colleges of education are essential partners in meeting the needs of refugee children. Teacher preparation programs can respond to the demands of schools characterized by language diversity and high levels of poverty. Attention to issues of cultural diversity, refugee populations, and development of

cultural competence would enhance the experiences of students in preparation to become teachers, as well as teachers in practice. Recruitment of students to teacher preparation programs who are CLD or refugees would be a benefit to refugee students and schools.

Collaboration with refugee families is essential. However, refugee families may come from settings that do not provide formal education or encourage the involvement of the family in school matters. Refugees may be uncertain about the new culture. What is expected, what is allowed, and what is customary are questions refugees may have about their involvement in the school.

The culture is new to refugees. They are attempting to fit into the new system. They may not have had previous experiences talking to teachers or coming to the school. They may be uncertain and fearful in coming to the school. Parents and children may not have attended formal schooling. They may be uncomfortable or confused with the new language and information that is presented to them. The services provided in schools in other countries may be very different than the services available in the United States. The values and priorities of refugee families for their children may be very different than those of the educators. Early education has the responsibility of serving as a bridge for refugee families.

REGGIO EMILIA APPROACH

The Reggio Emilia approach is an educational philosophy founded within the municipal preprimary schools and infant-toddler centers system of education in Reggio Emilia, Italy (serving children from birth through age 6). Named by *Newsweek* in 1991 as the best preschools in the world, these schools and the Reggio Emilia approach have been the source of much discussion and research in the early childhood field worldwide. The schools are part of a public system recognizing the fundamental rights of the child and the welfare of children and families as well as valuing democracy and coparticipation of educators, children, teachers, and community. Influenced by constructivism (Jean Piaget), social constructivist (Lev Vygotsky and Jerome Bruner) and progressive pedagogies (John Dewey), and the context and culture of the city, this philosophy is founded on the image of the child as capable and competent while learning in relationships with others, the environment, and place.

The Reggio Emilia Approach begins with the child and then is framed by educators, parents, and other adults within the community. Other notable elements in the approach are the role of the teacher, *pedagogista* (pedagogical coordinator), atelier (art studio/workshop), *atelierista* (studio teacher), family participation, group learning, the environment as the “third teacher,” *progettazione* (flexible planning projecting and reflecting in the curriculum), documentation, listening,

and the hundred languages of children. The Reggio Emilia approach is not any one of these characteristics described; rather, it is the integration of the characteristics seamlessly put together, offering ways for teachers to respond to children based on deep listening and serious consideration of children's actions, questions, and theories.

History

Reggio Emilia, located in the Emilia-Romagna region of northern Italy, is a diverse city of 170,000 inhabitants and the origination of the Reggio Emilia approach. Following the end of World War II, the first school (in Villa Cello) was started by a collective of women within the community and the National Liberation Committee (CLN), funded by the sale of a war tank, trucks, and horses abandoned by the German army and built out of the bricks from the destroyed buildings. These schools, representative of innovation, social awareness, and political activism, attempted to create an alternative to the traditional Catholic school models current at the time. The Reggio schools also offered a way to engage in education as a democratic process. They were parent run until 1967 when the municipality took over the administration of the schools.

As part of the postwar era, social policies influenced women to work as activists and this contributed to the development of the Reggio Emilia approach. The Nido Law (passed in 1972) supported women to participate fully in the postwar society by offering funding and construction of *nidi* (nests) for children ages 3 months through 3 years. This legislation ensured the care and education of young children as a public issue and responsibility, illustrating children's rights to high-quality early childhood experiences. This law has continued to evolve with additions such as increased paid parental leave and expanded provisions for early childhood. Presently, the municipality of Reggio Emilia continues to allocate city tax dollars to early childhood education, evidence of the city's continued commitment to high-quality early childhood education.

Loris Malaguzzi, founder of the Reggio Emilia approach, provided leadership to the schools and the related social and political engagement from 1946 until his death in 1994. His involvement began when he rode his bicycle to the site of the first school in Villa Cello, witnessing the commitment and collaboration of community members as they constructed the building. Following his work as a public school teacher and study in psychology, he joined the parents in Villa Cello, assisting in running the school and working as a teacher. His commitment to schools in Reggio Emilia and the Reggio Emilia approach continued throughout his career as teacher, director, and author/designer/collaborator with his colleagues of *The Hundred Languages of Children* exhibit (panels depicting the educational story of the Reggio Emilia approach including philosophical and pedagogical practices illustrated in photographs, children's work, video, and narrations) that has traveled the world.

Child as Capable and Competent

Central to the Reggio Emilia approach is the view of the child as capable and competent from birth. The implications of this image of the child are that the child is viewed as a resource, collaborator, and protagonist as well as an individual with rights (instead of the traditional perspective of the child having needs). This viewpoint supports children's ability to construct knowledge through communication, experience, and relationships.

Role of the Teacher

The teacher in the Reggio Emilia approach is a listener, rather than a speaker, present without being interfering, and a partner and guide in learning. The role of the teacher is dependent on the image of the child as capable and competent and is reciprocal as teachers also view themselves as capable and competent. This relationship encourages both child and teacher as protagonists and participants in the often-used metaphor in the Reggio Emilia approach of playing catch with the child. The teacher is a researcher, aware and attentive to the child, recording the child's theories,

actions, dialogues, and questions that inform teacher response developed during teacher group discussions as well as professional development and sharing across the field of education.

Pedagogista

The pedagogista or pedagogical coordinator role within the Reggio Emilia approach works across multiple schools influencing and being influenced by the work in each school. Responsibilities of the pedagogista include ensuring the quality of the programs in the system of infant, toddler, and pre-school programs in Reggio Emilia; administrative tasks synchronizing pedagogical, political, and social aspects of the system (working under the director of the system); and collaborating with other pedagogistas in the system and educators at specifically assigned schools. While this position has been in existence in this approach since the 1970s, there is a recognition that the position is constantly evolving and being rethought to best support the practice of learning for children, teachers, and families within the system.

Atelier and Atelierista

Atelier (art studio/workshop) and atelierista (studio teacher) are unique to the Reggio Emilia approach. The atelier is a place for children to practice and utilize symbolic languages to represent thinking, ideas, and theories as well as a place for teachers to understand children beyond the classroom. The atelierista is part of the teaching team in the school, contributes to documentation, participates in planning, and collaborates with the teachers.

Family Participation

Families are partners with both teachers and children in the Reggio Emilia approach. Collaboration with families is part of administrative decision making as well as curriculum development. Families engage daily with interactions in the school context including everyday school moments, field trips, events, and celebrations. Reflective of

the overall commitment to education as a democratic process, families are active in social and political issues impacting the community. The Reggio Emilia approach offers a way for parents and families to see and understand their children in a different context.

Group Learning

While traditionally education is often focused on the individual, the Reggio Emilia approach is enacted in the context of group learning. This context supports creativity, critical thinking, and problem solving within small peer groups, challenging the isolation of the individual while offering possibilities and people as resources to the children. Group learning creates spaces for children to realize new perspectives on their theories and answers while welcoming new questions and uncertainties to further children's thinking. Group learning also challenges the teacher to see beyond the child as an individual and understand the power of relationships.

Environment as the "Third Teacher"

In the Reggio Emilia approach, the environment is considered another teacher in the setting and great thought is given to the aesthetic qualities, overall feeling, and tone of the space. The environment is adaptable and often rethought by the children and teachers in order to provoke more thinking, questions, and ideas. Materials, space, furniture, structures, and objects all function to offer choice and possibility. For example, natural light is always part of the physical space and is frequently the catalyst for questions, theories, discussions, and projects.

Progettazione

Progettazione is an Italian term in reference to flexible planning, projecting, and reflecting in the curriculum that is part of the Reggio Emilia approach. This type of planning considers more than the curriculum and involves all facets within everyday school life, including connections to the

community. Further, it is not limited to the teachers but also includes parents and families. Progettazione supports negotiated learning and the contributions of the protagonists in the process (children, educators, families) utilizing communication practices and the system of relationships within the context. When teachers come together to engage in progettazione, they discuss the possibilities of a project and how the project might evolve while also recognizing the process is ongoing and dependent on listening to the children. Materials, spaces, provocations, theories, and possible situations are considered and proposed to the children while the teachers remain open to what could happen as the children engage.

Documentation

Documentation in the Reggio Emilia approach is meant to explain, making learning visible, and functioning as an instrument for interpretation, recalling, reflection, and revisiting, representing a shared remembrance and artifact of the community. The process of documentation includes collecting materials (audio, video, written notes, children's creation) during individual or group experiences and then recalling, revisiting, and interpreting. Documentation functions as a living document projecting, reflecting, and projecting again to inform curriculum and learning. The documentation process inspires meaning making for children and teachers within the school context and is representational of the school context and culture. Documentation is part of progettazione and furthers teaching and learning, evidence of the reciprocity between children and teachers within the Reggio Emilia approach. As visible listening, documentation encourages revisiting experiences to inform response and expand thinking for both teacher and child about a process, theory, or question. Documentation functions as teacher professional development as it is tied to planning and offers teachers a way to consistently interrogate practice. Personal and group evaluation are commonplace for children engaged with documentation as it provides a visual journey to children's

thought processes encouraging reflection and rethinking within theories and understandings.

Listening

In the Reggio Emilia approach, listening is seen as a metaphor representational of documentation and observation. Engaging in listening demonstrates the value each person has for the others as well as the openness to other perspectives and viewpoints. Listening includes interpretation, construction, and rethinking while also opening space for more questions, differences, and relationships.

The Hundred Languages of Children

The Hundred Languages of Children refer to the multiple forms of representation utilized within the Reggio Emilia approach. Examples of the Hundred Languages include (but are not limited to) drawing, sculpture, words, dramatic play, shadow play, music, movement, and painting. The use of the Hundred Languages trusts children as communicators who are able to cultivate their intelligence through use of symbolic representation.

REGGIO EMILIA APPROACH, ROLE OF THE ARTS IN

From the Reggio perspective, every child has at least “one hundred languages” available for expressing perspectives of the world. Some of those languages, such as visual art, music, dance, drama, and photography, are considered the “poetic” languages, cornerstones of this approach. Loris Malaguzzi, the founder of the Reggio Emilia preschool educational philosophy, believed an intervention for the dated model of schools was needed. One of his novel ideas was placing professional artists in every school, as a means for ensuring that all children receive quality art instruction. In fact, all preschools in Reggio Emilia now have a dedicated artist and artistic program in their school. This entry will examine practices in the atelier (arts studio), the role of the *atelierista* (artist-teacher), and the philosophical underpinnings of the role of the arts in the Reggio schools.

The Philosophy of the Reggio Emilia Approach

The educational philosophies of Johann Pestalozzi, Friedrich Froebel, and Maria Montessori were particularly important influences on the Reggio Emilia approach to the arts. Pestalozzi believed

that children were special in their own right and not just “little adults.” Pestalozzi proposed that children learn best through sensory exploration and in natural environments. Froebel, known for the creation of the kindergarten, thought that through the manipulation of materials and physical activity and games, children could form spiritual and abstract concepts such as unity in the universe and the combination of opposites. Montessori, like Froebel, also created schools for young children that centered on manipulating objects and playing games, but she first carefully studied children’s natural play behaviors to decide how materials and activities could best be applied. Reggio schools employ social constructivist art projects, which provide children opportunities to engage in sensory exploration within natural environments, which promote playful, creative learning.

John Dewey, Lev Vygotsky, and Gregory Bateson were also important influences on the use of artistic projects in Reggio Emilia schools. For Dewey, children’s play was highly desirable because it expressed a child’s current experience and understanding of the world. Vygotsky claimed that symbolic and dramatic play was essential for abstract thinking, as well as cognitive and emotional development, and that social engagement and collaboration with others were necessary in order to transform children’s thinking. Bateson’s theory of meta-communication stressed that multiple layers of learning provide the best type of education. Malaguzzi translated this belief to mean that non-verbal means of communication, such as visual art, would be especially valuable educational media in the schools. The famous adage “the map is not the territory” illustrates Malaguzzi’s assumption that traditional education is often flat in comparison with an artistic curriculum that can embrace subjectivity, curiosity, and creativity. Pestalozzi, Froebel, Dewey, Montessori, Vygotsky, and Bateson can all be seen as influences on the use of art in the Reggio Emilia approach. A common thread connecting these ideas is that artistic projects involve complex, multimodality processes that can potentially be fun, engaging, and meaningful for children.

The Atelier

The Italian word *atelier* means “artist studio.” Malaguzzi incorporated the atelier into the pre-school design starting in the early 1960s. In the 1970s, he also added ateliers to the infant–toddler centers and mini-ateliers into individual classrooms. Malaguzzi proposed that the poetic languages contain an “alphabet”; and, if practiced over an extended period of time, this alphabet will evolve into a fluent language.

Vea Vecchi, one of the first atelieristas to work closely with Malaguzzi, has written several books recounting her experiences of working with children in the Reggio Emilia schools. Vecchi emphasizes that the atelier is a place to *sensibly* introduce artistic techniques and artistic thinking to children. The atelier should be a place where children have extensive experiences in creating art works from both observation and imagination. Children in the Reggio Emilia schools display high levels of artistic skill because they have been provided expert instruction and guidance in using tools, materials, and techniques for art. However, the quality of the art produced is not actually what is important. Rather, children’s art works are considered “documents” used for further research into children’s learning potential. This documentation is a key aspect of the Reggio Emilia approach, and children’s art provides a visual means for examining and guiding children’s perspectives and thought processes.

The Atelierista

The atelierista is a professional artist who is not trained as a formal schoolteacher. The role of the atelierista is to prepare engaging and challenging art projects. As the children work with the artistic materials, the atelierista observes their actions and explores theories regarding their thinking processes. These theories guide new ideas or, in Reggio Emilia school parlance, are referred to as “provocations,” which are then used to stimulate and guide children to advance their artistic thinking. Indeed, what is distinctive and unique regarding the Reggio Emilia approach is that the

atelierista thinks like an artist and is therefore able to interpret children’s creative processes from an artistic perspective.

The atelierista, however, is not the sole expert on deciding new directions for atelier provocations—teachers, parents, adults, and children are all equally considered competent at this task because they each have their own unique perspective, and it is from this mixing of perspectives that new atelier ideas arise. In contrast to traditional education, learning outcomes in the atelier are emergent rather than prescribed in advance. By closely observing and documenting children’s work as it occurs over time, both atelieristas and teachers are able to dynamically respond to the unique pathways of each child’s artistic and intellectual growth.

Interweaving of Languages and Ateliers

The atelier is synonymous with the Reggio Emilia school. Indeed, the Reggio Emilia school is a collection of diverse yet interrelated ateliers. Because all the languages of learning have aesthetic qualities, ateliers have been created in multiple subject areas, from music to biology to writing and mathematics. In Reggio Emilia schools, learning processes themselves are considered fundamentally aesthetic. The atelier provides the aesthetic vehicle for learning, allowing children to develop empathy with their environment and foster care and quality in creating, while nurturing the ability to work collaboratively with others in the pursuit of collective meaning.

REGULATORY AGENCIES

Regulatory agencies in early care and education serve an important function in the protection of children in out-of-home early care and education settings. Moreover, they serve as important partners in efforts to enhance overall program quality to ultimately improve child outcomes.

Unlike K–12 education where schools typically operate under the governance of local school boards or similar structures, services for children from birth to age 5 are offered in an array of settings including child care centers, schools, and family child care homes in communities and states throughout the United States. Services are provided under the auspices of for-profit businesses, nonprofit organizations, faith-based organizations, and education agencies. Therefore, the complexity of delivery models has necessitated the creation of policies to ensure the health, safety, and well-being of children in out-of-home care regardless of the setting. Regulatory agencies serve to carry out what is typically referred to as *licensing policies* or *standards* enacted for this purpose.

The Role of Regulatory Agencies

Standards for high-quality care have been defined in *Caring for Our Children: National Health and Safety Performance Standards: Guidelines for Early Care and Education Programs* (3rd ed., 2011) by the American Academy of Pediatrics. However, there are no unifying policies requiring adherence to these standards for all early childhood education (ECE) programs throughout the

country. Some federal funding streams impose requirements that may exceed a state's policies as a mechanism to ensure conformity with appropriate practices but applicability is limited for targeted funded populations. Each state defines a threshold or baseline of protection for children with some states requiring more stringent standards and enforcement. These policy standards reflect the state or local community's philosophy and the prevailing political environment. Local ordinances may be enacted that exceed state standards. Therefore, the role of regulatory agencies differs depending on the state and local ordinances created to oversee and regulate ECE settings.

The limits of authority by regulatory agencies are dictated by the state and local standards. These standards typically address areas such as facility health and safety, staff education and credentials, background screening, staff preservice and in-service training, adult to child ratios, group size, health requirements and medical care, nutrition, behavior guidance and discipline, activities and materials/equipment, child assessment, transportation, and specific regulations for age groups (infants and toddlers, preschool and school-age children) and care for children with disabilities or other special needs. The extent to which these areas are addressed in licensing standards varies considerably as do enforcement practices.

For example, all 50 states require that child care centers are inspected prior to licensure according to the National Association for Regulatory Administration (NARA) in its Child Care Licensing Programs and Policies Survey in 2011. However, some states reported that inspections are announced in advance and some reported that inspections are unannounced, which means that the owner/operator may or may not know when an inspection will occur. The frequency of onsite inspections to monitor for compliance with program standards also differs by state ranging from more than three times per year for four states to as few as once every 2 years for five states. National experts recommend no fewer than two inspections per facility per year to include child care centers, family child care homes, or group homes.

There are also ECE settings that are exempt from regulation in some states. For example, some states exempt faith-based programs from licensing requirements based on separation of church and state. Additionally, recreational programs such as Boys and Girls Clubs, among other programs serving younger children, are exempt from licensing in some states according to NARA. The definition for these exemptions is typically articulated in state statutes and may require other evidence of child safety and protection in lieu of licensure.

Federal Policy

While there are no national policies governing all early care and education programs, the largest source of funding for early care and education is the Child Care and Development Block Grant (CCDBG), which was reauthorized by Congress in 2014 (Pub. L. 113-186). It is important to note that this policy lever aims to improve the quality of early care and education programs requiring basic health and safety protections for children served by taxpayer dollars, regardless of the setting. Children eligible for services under CCDBG are typically those from low-income households whose parents or caretakers meet defined eligibility criteria.

The reauthorization of CCDBG addressed several areas. Some of those areas include duties that are delegated to regulatory agencies including the following:

- Comprehensive background checks will be required for providers who are licensed, regulated, or registered under state law, which includes a fingerprint check against state and federal records, child abuse registry, and sex offender registry.
- States will be required to explain how the use of federal funds in unlicensed care will not endanger the health, safety, or development of children.
- Child care programs will be required to be inspected before a license is issued and conduct

at least one unannounced annual inspection for licensing compliance, health, safety, and fire standards. Unlicensed programs would also be subject to an unannounced inspection for health, safety, and fire standards.

- States will be required to ensure that providers have training in several areas addressing the safety, health, and well-being of children.

Among other provisions, the legislation also addresses issues of child care quality by increasing the percentage that states must spend to improve quality from 4% to 9% of their allocation over 5 years, with an additional 3% for quality activities for infant and toddler care. Other efforts to improve quality require states to have policies related to adult-child ratios, group size, and staff qualifications. CCDBG also requires states to engage in one of several specific activities to improve quality utilizing the quality set-aside funding. While CCDBG is specifically targeted to serve eligible children, other provisions in the legislation impact the early care and education system in states to ultimately improve the quality of services available for all children.

Quality Improvement

Regulatory agencies also play an important role in quality improvement systems (QISs) in states as compliance with child care licensing standards often serves as an entry point into a QIS. Such systems aim to improve the quality of early care and education through established standards with incentives for compliance at increasingly higher levels. QIS standards typically address staff qualifications and professional development, curriculum and learning activities, child assessment, and children's health and family engagement, according to an issue brief from the Department of Health and Human Services, Office of Child Care in November 2011.

RELATIONAL POWER

Children's development and all they achieve in the early years of life occur in the context of relationships. Relationships are essential as children form concepts about the world and their place in it. Children form relationships with a variety of people such as parents, other family members, caregivers, peers, and a range of others with whom they interact on a less frequent basis. This entry considers the relationship of children with their primary caregivers, with teachers, and with peers. These relationships are powerful and their quality, both positive and negative, greatly influences how children function as they go through life.

Attachment

The earliest relationship almost all children form is with a parent or parent substitute. A large body of research has examined the formation of attachment, the emotional connection between parent and child, which, when secure in quality, should lead to feelings of security and trust in the child. Young children who experience consistent and loving care trust that they will be protected as they explore their environment. Such exploration, in turn, leads to increasing confidence in children that they are capable and competent. Attachment research has utilized the theory of John Bowlby, who believed that the early bond between mother and child has a profound influence on later development. More recent research has also underscored the importance of other primary caregivers such as fathers and consistent teachers, and that attachment is not simply determined by the primary caregiver's behavior but is bidirectional; the child is as much a partner in the establishment of the early parent-child relationship as is the adult.

Almost all children become attached to their caregiver, but the quality of that bond determines the type of attachment that is formed. Researchers have identified different attachment styles, including secure attachment, ambivalent-insecure attachment, avoidant-insecure attachment, and disorganized attachment. Parents of securely attached young children are nurturing, dependable, and responsive to their youngsters' needs and, as a result, such children are thought to form a mental template for relationships that is positive. They face the world with confidence and self-assurance. As toddlers and preschoolers, securely attached children tend to be socially competent and popular with their peers. Furthermore, because they have a positive bond with their primary caregivers, they are much more likely to engage in the behaviors their caregivers encourage.

Some children, on the other hand, experience a range of challenges, including primary caregivers who are themselves insecure, depressed, rejecting, neglectful, or abusive. Such circumstances have far-reaching impact. Children's earliest interactions

are thought to set the stage for later relationships. When these early experiences are not positive, if these children do not have secure relationships with other important caregivers, and if they do not experience an intervention to improve the quality of relationships, later interactions with significant others are likely to be negative as well. For instance, children who have an ambivalent attachment to their mother tend to respond aggressively in later interactions; children with avoidant attachment tend to be withdrawn; and children with disorganized attachment often show both aggression and withdrawal.

Researchers have found a strong relationship between secure attachment and positive outcomes and insecure attachment and negative outcomes in virtually all aspects of children's subsequent development. Research on resilience suggests, however, that even when children experience less than ideal parenting, they can learn positive interactions through other significant adults in their lives who intervene at opportune moments. Furthermore, children can and do form multiple attachments, such that if one of these relationships is insecure in quality, it can be offset by relationships with others that are secure in nature.

Relationships With Teachers

In recent decades, an increasing number of young children have spent much of their day in child care settings; thus, many children also interact on a daily basis with child care teachers. Children can form deep relationships with consistent, responsive teachers; these relationships, in turn, have long-lasting effects. Various studies have examined this effect of the early childhood teacher on children through eighth grade. Children who have a warm, close relationship with their early childhood teachers adjust better to elementary school, performing better both academically and socially, than children who did not have a positive relationship with an early childhood teacher. In addition, as mentioned briefly earlier, a positive attachment with a teacher can help to ameliorate the negative effects of insecure attachment with

the primary caregiver. Such responsive teachers tend to be found in high-quality child care programs, which foster sensitive interactions and provide for children the kind of security that encourages them to explore and experiment within their school environment.

On the other hand, children whose relationship with their teachers is conflict ridden or characterized by dependency tend not to be well prepared for subsequent school experiences. Researchers have found that such children were less academically ready and had a much higher rate of adjustment problems in elementary school than children who had close and positive relationships with their preschool teachers. Another relevant research finding is that toddlers, who are particularly sensitive to change, do not fare well when there is a change in primary caregiver. Children who were between 18 and 24 months of age when placed in the care of a new teacher tended to be more aggressive at age 4. This is particularly disturbing, given the high rate of teacher turnover in child care and the decision in some infant-toddler programs to move children into a new classroom with a new teacher when they reach certain age milestones. Continuity of caregivers is important for children of all ages, but very young children are especially vulnerable to the loss of a teacher with whom they have developed a relationship. Children who experience a warm, affectionate, consistent relationship with preschool teachers are significantly more likely to be successful in elementary school than their peers whose relationship with teachers is characterized as conflict ridden or dependent.

The importance of a positive relationship with teachers is emphasized in a widely used and well-researched quality assessment tool, the Classroom Assessment Scoring System (CLASS). In this instrument, quality is measured along three domains: (1) emotional support, (2) classroom organization, and (3) instructional support. Emotional support is evaluated through observation of classroom climate, including whether teachers and children have positive relations with each other, enjoy being together, and are respectful of each other. It is also examined in relation to the

teachers' sensitivity to the children, including their consistent responsiveness to the children, their ability to provide appropriate support, and their creation of a safe environment in which children are able to explore and learn. Finally, emotional support is measured by whether teachers take the children's perspectives and points of view into consideration, encouraging them to share their ideas and supporting their autonomy.

Nationally representative research on the impact of emotional support in the classroom shows that high-quality teacher-child relationships can be a moderating factor contributing to children's overall academic and social achievement, particularly for children who are at risk of school failure. One study found that high levels of emotional support in pre-K classrooms predicted academic, social, and language development through the kindergarten year. The fact that the CLASS gives equal emphasis to relationships as it does to academic factors underscores the importance of relationships in children's lives.

Relationships With Peers

One of the most significant tasks of childhood is to establish relationships with other children, as noted in the highly respected report of the National Research Council, *From Neurons to Neighborhoods*, edited by Jack Shonkoff and Deborah Phillips. Peers take on an increasingly important role in each other's development as children enter the preschool years. Many children are in group-care settings from a very early age and thus have numerous opportunities to interact with their age-mates. A small but growing body of research documents infants' and toddlers' keen awareness of other children and how they begin to show preference for certain others. By preschool age, many children develop a special relationship with one or two children, using terms like *best friend* to describe their budding affinity. Early friendships are both meaningful and enduring. Considerable research has examined peer interactions and described some of the long-term effects on children's development.

Preschool-age children who are competent in their interactions with peers demonstrate qualities such as sharing, engaging in pretend play, turn taking, and negotiation. This social competence, in turn, correlates favorably with positive developmental outcomes. Children who have had positive experiences with peers in preschool tend to continue to be socially competent in elementary school and, according to one study, continue on that trajectory into adulthood. There is also growing evidence that friendships are linked to school adjustment. For example, when a child starts elementary school with a preexisting friendship, that child adjusts better to the new school. In addition, children who make new friends in their new school tend to feel more positively about school and do better academically than children with fewer friends.

Some children have few or no friendships and appear to be rejected by their peers. Rejected children may be overly aggressive or they may be shy and withdrawn. When rejection occurs over a period of time rather than as a transient experience, children tend to have a difficult time adjusting to school. Furthermore, such children often do poorly both socially and academically in school and may grow up to be adults with mental health problems.

Adults play an important role in fostering positive peer relations. Generally, when children are securely attached to their primary caregiver(s), they tend to have harmonious peer relations. Similarly, teachers can encourage children's relationships with each other. Because children do not naturally know how to interact appropriately in a group, the astute preschool teacher will facilitate positive interactions through coaching, modeling, interpreting, and explaining the emotions of others and encouraging children with regard to positive methods of engagement. When children feel their classroom is harmonious and safe, they are much more likely to engage in positive interactions with each other than in classrooms where teachers tend to be cold and threatening. Researchers have found children's interactions with their peers to be linked to their relationship with the teacher; if teachers are nurturing and encouraging, children tend to engage in positive peer interactions. Early childhood teachers

also can provide materials and activities that foster social participation and support children's emerging social competence in their relationships with peers.

Conclusion

Early childhood is the time in which the quality of relationships most profoundly impacts children's formation of attitudes about others, themselves, and the world they live in. Whether with primary caregivers, teachers, or peers, positive relationships have the potential to bolster self-esteem and encourage engagement in the environment, while negative relationships may dampen social and academic potential. Relationships are, indeed, powerful.

RELATIONSHIP BUILDING

Many variables influence how children develop relationships and how well their interaction styles work for harmony in relationships. Infants younger than 1 year were observed to choose animal puppets they have observed *helping* rather than *hindering* another puppet. Toddlers show clear abilities to help others.

Some factors are fundamental for the mature development of empathy, sharing, cooperation, and helpfulness. Early primate research revealed that maternal love is crucial for later peer relationships. During the 1950s, Harry Harlow and Robert Zimmerman reared baby monkeys with one artificial mom covered in soft terrycloth and one of wire with a nipples bottle providing milk. Monkeys clung constantly to soft cloth moms *unless* they needed a swig of milk. These isolated monkeys bit themselves, rocked compulsively, and could not play well when brought together with peers.

Secure Attachments: Roots for Positive Relationship Building

Psychiatrist Margaret Mahler observed that baby normally experiences an initial blissful feeling of

oneness with mother, at about 1 year, then a “love affair with the world” when baby feels that the world *holds* the baby as mother did at first. The choreography of the transition to toddlerhood includes *relationship contradictions*: struggles to reconcile oneness and separateness; holding on/letting go; flinging away/clinging; darting away/shadowing; anger/sadness; no saying and temper tantrums (Kaplan, 1976). Caregivers weather such contradictions with patience and kindness, or child–adult relationships can become frayed.

Mahler noted that children with disturbed relationships were disrupted in the process of individuation/separation and failed to recognize mother as a beacon of orientation. They did not develop a sense of “constancy”—an inner model of the *nuances* of interpersonal behaviors present by 3 years. Louise Kaplan (1976) posits that children who develop a sense of constancy understand that persons are neither “bad” nor “good,” and they learn to accept that peers and parents are neither saints nor demons, to maintain the wholeness of self and other even during times of less satisfaction, and to “unite love and aggression” (p. 191).

Donald Winnicott proposed that an essential milestone for early development is *concern for others* when children respond to others’ unpleasant or painful experiences with empathic responses. In his psychoanalytic practice, mother–child relationship difficulties from the earliest times were at the heart of troubles of every child with relationship difficulties.

Working with delinquent youngsters, psychoanalyst John Bowlby noted in 1988 that without early mother support and empathy, children grow up expressing aggression, delinquency, and promiscuity. “A child’s anger is frequently an expression of frustrated desire for love and care, and anxiety is often a child’s uncertainty about the parents’ continued availability” (p. 58).

After working with Bowlby in England, Mary Ainsworth (initially in Uganda and later in the United States) studied positive attachment behaviors of babies: smiling when mom comes into the room, reaching out and/or calling out to be picked up, snuggling and molding/sinking onto mom’s

body, able to play well with toys after mother’s return, able to give stranger a dazzling smile *if* safely snuggled in mom’s arms. Ainsworth and colleagues carefully observed in-home mother–infant interactions and then invited the dyads into the laboratory when babies were 1 year old, for a 20-minute strange situation test, involving two brief separations from mom and two interactions with a stranger. *Reunion* behaviors when mom reenters the room were coded as secure (66%), ambivalent/insecure (12%), and avoidant/insecure (12%). Later, a disorganized/insecure code was further added for when babies show inconsistent contradictory behaviors.

Avoidant infants look “cool,” but their heart rate and stress hormone levels suggest that avoidant children are stressed by separation from their special caregiver, despite how well they seemingly adjust (Fraley, 2012). *Disorganized* children have caregivers who have been emotionally detached, unpredictable, frightening/frightened, or harsh. Richard Fearon and colleagues’ (2010) meta-analyses of 69 research studies confirmed that insecure/disorganized attachment is associated with later elevated risk for more reactive and proactive aggressive behaviors with peers. The following is an example of parenting behavior observed by Alice Sterling Honig that appeared likely to eventuate in later child attachment difficulties:

Starting outward, mom sat with her screaming baby on her lap with baby facing away from mom. When I gently suggested that she put baby to shoulder with closer touching, mom did so; for a minute, baby quieted. As baby began again to wail, mom resettled baby on lap facing outward and sat with a far away look in her eyes, silently, with no soothing gestures nor attempts to interact with baby.

Early attachments serve as an *unconscious template* for later social relationships. A secure IWM (internal working model) develops outside of consciousness with the main purpose of assuring adaptive regulation of negative arousal when a child is feeling insecure or distressed. Having

learned that caregivers are sensitive, flexible, trustworthy, and available, securely attached infants develop more self-efficacy, self-regulation, and self-confidence. Their friendly overtures to peers are more likely to be accepted, and they resolve peer conflicts peaceably.

Contrast this with preschoolers initially identified in infancy as “avoidant/insecure,” who behaved as *bullies* when paired in a playroom with peers who had been insecure/hesitant babies. The bullied preschoolers sometimes even invited more bullying (Sroufe & Fleeson, 1986). Teachers, ignorant of infant classifications, rated the secure preschoolers comparatively as less aggressive, showing more empathy for others, more able to sustain positive peer interactions, and more popular with classmates. L. Alan Sroufe, Elizabeth Carlson, and Shmuel Shulman later reported that at a summer camp, counselors rated those initially secure children at age 11 as more socially competent, with more close friendships than formerly anxiously attached peers.

Attachment insecurity predicts later relationship troubles. Infants with insecure attachment at 12 months were significantly more likely to exhibit consistent *increases* in difficult conduct and aggression. Securely attached babies, *even when in high-risk environments* with maternal depression, high financial stress, and delinquency of parents, were *less likely* to develop a trajectory of high behavior problems into preschool (Keller, Spieker, & Gilchrist, 2005).

Controlling for maternal education, child aggression was higher when moms had lower education. In a study published in 2014, Maeve Cyr, Dave Pasalich, Robert McMahon, and Susan Spieker revealed the power of secure early attachment to *protect* against preschooler aggression in relationships through analyses of strange situation attachment data for 82 mother–infant dyads at 12 months and observations when children were 4.5 years old. During the “child’s game,” moms followed the child’s lead in play. In the “parent’s game,” moms chose the course of play. In the “cleanup phase,” moms directed children to put away toys and clean up the room. Mothers’ *criticism* of their

preschoolers later correlated positively with child relationship aggression in Grade 1 for children with initial insecure attachment, but *not* for children with initial secure infant attachment. Cyr conceptualized attachment as a lens by which children perceive negative aspects of parenting, and that lens protects securely attached children so they are less vulnerable to harsh parenting practices.

Insecure IWM can lead to dysregulation, rigidity, or negative appraisals of situations—an inability to modulate the control of feelings, emotions, and actions appropriate to the social situation. Ego resiliency arises from children’s experience of supportive parents as well as positive valuing of secure attachment. College-age adults secure in romantic relationships were more likely to recall their childhood relationships with parents as having been loving and affectionate.

Temperament Troubles

Three major temperament styles have been observed in children: easygoing, feisty/intense/irritable, and shy/slow to warm up. Cautious children tend to need more adult coaching in group entry skills to engage with peers and more support for *sustaining* play sessions with peers. Children with intense temperaments may have more difficulties in social relationships.

Effects of Child Gender and Attractiveness

Gender impacts relationship building. In preschool, children prefer playing with a child of the same gender. Boys may declare “Girls can’t be firemen!” and refuse to include girls in their play scenarios. Attractive children are more often chosen as playmates. Aggressive children are disliked and rejected by preschool peers.

Parenting Style

Longitudinal studies of Diana Baumrind’s three major patterns of parenting reveal that parenting styles strongly affect relationships. Adolescent sons

of rigid, power-assertive, harsh (authoritarian) parents were unfriendly, easily annoyed, and deceitful and alternated between aggressive behaviors and sulky withdrawal. Youth whose parents had been quite permissive proved to be domineering, quick to anger, and aggressive in relationships. Children of involved, warm, responsive, and firm parents (authoritative) showed purposeful cooperative behaviors with adults and maintained friendly relations with peers. A fourth type, uninvolved parenting, has been associated with later impulsiveness and aggression as well as moodiness, low self-esteem, delinquency, and relationships with troubled peers.

Effects of Family Situations and Neighborhoods

Other early risks predict later violence. Extreme poverty, parent in prison, and young teen parenting contribute to worrisome child behaviors, including heightened aggression. Living in dangerous neighborhoods, parents may confine children indoors to keep them safe and protect them from gang violence.

High parent conflict and custody disputes lead children to struggle with relationships with parents and peers. Young women from divorced families are more likely to have difficulty with heterosexual relationships.

Longitudinal British studies of children adopted after early infancy from grossly depriving Romanian orphanages revealed long-term negative effects, including indiscriminate friendliness with strangers and social difficulties (Rutter et al., 2010). Yet, nurturing adoptive parents have indeed reared adopted children with positive relationship outcomes (van Ijzendoorn & Juffer, 2006).

Effects of Stress, Abuse, or Trauma

Child trauma can arise from multiple sources, including chronic illness, parental drug abuse, war-time terrors, sexual molestation, watching a loved parent being assaulted, and schoolyard or cyber bullying (Honig & Zdunowski-Sjoblom, 2014). Stress affects children's neuroendocrine-immune

network. Abusive parenting changes brain structure. Cortisol (a stress hormone) disrupts the hippocampus, the brain center for memory, and increases the size and activity of the amygdala, the brain's main area for threat perception and fear responses, so children react more to situations they perceive as threats. For example, a troubled preschooler whirled around with angry face and clenched fists, ready to attack a peer who had brushed past him lightly while happily running toward an available red tricycle (Honig, 2010).

Sibling Relationships

As young as 6 months old, children have been noted to respond with jealousy and even physical attacks on another baby their mom is cuddling. Feelings of having been displaced and reaction to loss of exclusive parent attentiveness can result in dysfunctional relationships. Parent preference for one sibling as "smarter" or "prettier" can lead to lifelong family estrangements.

Strategies to Promote Positive Relationships

Harlow increased relationship abilities of his isolated, traumatized monkeys by providing extensive opportunities for the monkeys to play with younger peers. Poorly adjusted human children, rejected by peers, also show more positive relationships when paired with younger children.

Temperament is not destiny. In Holland, home visitors taught low-education mothers of highly irritable babies how to anticipate difficulties and soothe their infants. By 1 year, those babies were mostly securely attached (68%) compared with lower rates (28%) for babies whose mothers were randomly assigned as controls (van den Boom, 1997). Teachers who reinforce *specific* prosocial interactions enhance relationship harmony (Honig, 2004). When a teacher described aloud and then wrote down observed helpful interactions on paper slips and stored these in a "kindness jar," the children themselves started noticing more and reminding the teacher to include prosocial actions (Honig,

2002). Vivian Gussin Paley (2001) promoted children's willingness and ability to include rather than exclude peers by inviting a child daily to dictate a story and choose peers to act out scenario roles. In another study, second graders daily shared with teacher positive peer interactions they saw in classroom, lunchroom, or hallways. The researcher tallied twice as many positive interactions after one month, but no change in a randomly assigned control classroom (Honig & Pollack, 1990).

Enhancing young children's *sense of control* promotes more positive interactions (Mittal & Giskevicius, 2014). William Damon (1988) suggests inviting volunteers to talk in classrooms about their efforts (e.g., coaching children with disabilities to swim together) to promote prosocial relationships. Teaching children *distraction and distancing* techniques helps them resist a current temptation (one marshmallow) and wait, in order to get two treats. Such effective self-monitoring techniques resulted decades later in better life outcomes including increased social relationships (Mischel, 2014). Myrna Shure (1996) advocates techniques that galvanize children to choose and use *problem solving skills* (such as asking oneself "What will happen IF") to resolve hurtful or angry relationships. J. Ronald Lally and colleagues found that high-quality child care plus home visitations to enhance family relationships, for single teen parents, led to reduced juvenile delinquency and recidivism rates 10 years after early intervention for those who had attended the program in comparison with control youth.

Psychiatrist Bruce Perry (1993) trains therapists in healing techniques to reduce traumatized children's "freeze, flight, or fight" responses. Providing a climate of safety and trust, therapists help children "experience simultaneous contradictory feelings (e.g., anger and love or fear and rage) "to mitigate defensive avoidance and enhance positive social relationships (Briere, 1992, p. 88).

Conclusion

Building positive encounters in families, classrooms, and social groups requires promoting early

secure attachments. Additional efforts include teaching therapeutic tools to promote children's cognitive executive functions and providing practice and encouragement for children to use problem solving and emotional "cooling" skills to de-escalate and resolve interpersonal conflicts and thus enhance prosocial relationships.

RELIABILITY AND VALIDITY IN CHILD ASSESSMENT

According to the National Association for the Education of Young Children (NAEYC), the purpose of child assessment is to evaluate young children's strengths, progress, and needs. NAEYC further notes that assessments fulfill multiple purposes such as helping to make informed decisions about teaching and learning, identifying developmental red flags or other significant concerns that may require follow-up diagnosis and intervention, and improving educational programming or interventions. The assessment of young children is widespread in today's early childhood context. For example, early childhood educators are often responsible for choosing, administering, interpreting, and using the results of child assessments. Many early childhood educators report feeling overwhelmed and frustrated with these responsibilities.

The purpose of this entry is to assist readers in becoming familiar with two important concepts associated with child assessments, specifically reliability and validity. Reliability refers to the consistency of scores generated by an assessment, whereas validity refers to whether an assessment is assessing what it claims to assess. Reliability and validity are necessary to answer important questions such as

“How consistent are scores on child assessments?” and “What does this child assessment really measure?” While the choice of a particular type of assessment depends on the purpose, the assessment ultimately used should be selected on the basis of reliability and validity. A detailed review of the different types of reliability and validity is presented as well as guidelines used to evaluate reliability and validity in child assessments.

Reliability

As noted earlier, reliability is synonymous with consistency, and an assessment is considered reliable if it generates similar results over repeated time points regardless of who administers the assessments and/or alternative forms used. Reliability coefficients range from 0.00 to 1.00, with higher coefficients reflecting greater levels of reliability. There are several types of reliability, including test-retest, interrater agreement, parallel forms, and internal consistency. Each of these types of reliability has strengths and limitations and is discussed in detail. It is suggested at least one type of reliability, ideally more, should be considered when evaluating child assessments.

Test-Retest Reliability

Test-retest reliability is established by administering the same assessment to the same sample at two different time periods. The correlation between the two scores represents the degree to which the test is stable over time; high correlations reflect higher reliability. In general, short retest intervals generally produce higher reliability estimates. It is recommended that retest intervals not exceed 6 months. However, this interval should be shorter (i.e., less than 1 month) with young children due to their rapid developmental changes.

There are some reported problems associated with test-retest reliability. For example, practice gained during the first administration of the test might influence retest scores. Another issue is memory; that is, young children may rely on their memory from the first administration and thus

inflate the reliability estimate. Due to these issues, it is recommended that reviewers not rely solely on test-retest reliability when evaluating assessments.

Interrater Agreement

Interrater agreement is typically calculated by the percentage of agreement between raters/observers. If the data are continuous, the researcher would calculate the intraclass correlation. A type of interrater agreement statistic is Krippendorff's alpha, which can be used with all types of data (i.e., nominal, ordinal, interval, and continuous). An issue related to interrater agreement is the need for multiple raters/observers and hence the necessity to train multiple people, which in turn increases time and effort.

Equivalent/Parallel Forms

Equivalent/parallel form reliability is assessed by administering two equal alternative forms of one assessment. A researcher creates equivalent/parallel forms by randomly dividing one assessment into two equal parts that are administered to a sample at the same time. Reliability is calculated by the correlation between the two forms. Some issues associated with this type of reliability include needing a large number of items, as well as the assumption that the random parallel forms are equal and the two equivalent/parallel forms are assessing the same construct. Equivalent/parallel forms are only useful if the researcher is planning to administer two different, but equal, versions (i.e., Form A and Form B) of one assessment.

Internal Consistency

Although internal consistency is calculated in a variety of ways (e.g., coefficient alpha, split-half, Guttman, parallel), they all yield information related to the homogeneity or the degree of consistency of the content within a single assessment. Some internal consistency methods rely on a single administration of an assessment (e.g., Cronbach's alpha), while others rely on more than one administration (e.g., split-half). High estimates of internal

consistency indicate the items on the assessment are indeed assessing the same construct/trait. However, extremely high internal consistency scores may indicate redundancy within an assessment.

Factors Affecting Reliability

There are several factors (e.g., length, representativeness, measurement error) that could potentially affect reliability scores in child assessments. For example, assessment length has been shown to affect reliability—the longer the assessment, the more reliable the assessment. Another factor is item representativeness—the more the items represent the construct or trait being assessed, the greater the reliability. Finally, inconsistency in assessment results can often be attributed to measurement error. Measurement error is either random or systematic. Random error is caused by any factor (e.g., mood of participant, poorly defined item, item ambiguity) that randomly affects the measurement of a variable; whereas systematic error is caused by any factor (e.g., assessment not used correctly, response format, interviewer bias) that systematically affects the measurement of a variable.

Guidelines to Evaluating Reliability Associated With Child Assessments

It is important to note that test-retest, interrater agreement, equivalent/parallel forms, and internal consistency are not equivalent forms of reliability and as such it is suggested that multiple forms be used when evaluating the reliability of assessments. In addition, the reliability procedures and samples should be reported in detail in order to evaluate the strengths and weaknesses of how reliability was calculated. For example, sample characteristics are important for assessment evaluation because the reported reliability coefficient is only applicable to samples that are similar to the one used for the calculation of the reliability coefficient. Finally, researchers have recommended .70 to .80 as adequate levels of reliability in most research. However with high-stakes assessments, a higher reliability, such as .90, is required.

Validity

The central question with validity asks, “Is the assessment assessing what it is intended to assess?” Procedures for determining test validity evaluate the relationship between assessment performance and other indices of the behavior in question (e.g., intelligence, math achievement). As with reliability, different methods are used to establish validity. The different types of validity include construct validity (factor analysis, multitrait-multimethod matrix), content validity, and criterion-related validity (predictive, concurrent). A thorough validation of an assessment typically involves several different types of validity; however, the different types of validity are distinct and require different evidence.

Construct Validity

Construct validity is the extent to which an assessment measures a theoretical construct/trait (e.g., intelligence, verbal fluency, creativity). Based on theory, predictions are made about how performance on an assessment should relate to other variables. That is, construct validity is demonstrated when assessments are related to variables to which they theoretically should correlate (i.e., convergent) and do not relate to variables from which they should differ (i.e., divergent). Procedures for examining construct validity include correlations between assessment scores and a criterion score, factor analysis, and/or multitrait-multimethod matrix analysis. If high construct validity is shown in a child assessment, then one can be certain that the items represent one underlying construct.

Factor Analysis

Construct validity can be established through factor analytic techniques such as exploratory and confirmatory factor analysis. Factor analysis is a set of statistical techniques that reduce a large amount of information into a smaller, more manageable size. Factor analysis is used to confirm whether or not an assessment is measuring the construct it is purported to measure.

Multitrait-Multimethod Matrix (MTMM)

Another technique to establish construct validity is the multitrait-multimethod matrix (MTMM). The MTMM is basically t traits measured by m methods. The different types of methods can be instrument based (e.g., Guttman, Likert, Thurstone), occasion based (e.g., times 1, 2, 3), and/or informant based (e.g., self, teacher, parent). The traits and methods combine to form three different correlation matrices: homotrait-heteromethod (same-trait-different-method), heterotrait-homomethod (different-trait-same-method), and heterotrait-heteromethod (different-trait-different method). Validity is established by examining the correlation matrices to determine convergent and divergent validity.

Content Validity

Content validity is the extent to which the items on an assessment are a representative sample of the larger construct in question. This type of validity is a matter of judgment. Content validity is typically determined by subject-matter experts or assessment users through a review, a logical analysis, or both.

Criterion-Related Validity

Criterion-related validity assesses the relationship between assessment scores and some other criterion. High validity is demonstrated by a strong correlation between scores and a related criterion such as a validated assessment of the same construct. There are two types of criterion-related validity: predictive and concurrent. Predictive validity is established by comparing the scores on a child assessment with scores on another child assessment in the future; whereas concurrent validity is established by comparing the scores on one child assessment with the scores on another child assessment, both assessing the same construct, taken around the same time.

Factors Affecting Validity

There are several factors that can affect the validity of child assessments. For example, an assessment could consist of an inadequate number

of items or poorly written items and therefore affect construct validity. Another threat to validity is the lack of appropriate item analysis procedures. Insufficient validation analysis is a major threat to validity and includes only examining one type of validity instead of multiple types.

Guidelines for Evaluating Validity in Child Assessments

Validity of child assessments should be an accumulation of evidence. For example, when validating an assessment, a researcher may examine several different forms of validity such as content analysis, factor analysis, comparing correlation coefficients, and multitrait-multimethod matrices. In other words, validity is a continuous systematic gathering of information from a variety of different sources. It is important to note that an assessment may be valid for one purpose but not for others.

Conclusion

In summary, information about reliability and validity is important when determining the appropriateness of an assessment. If an assessment is proven to be unreliable and not valid, then the results of that assessment cannot be trusted. It is worth noting that an assessment can be reliable but not valid; however, an assessment cannot be valid without being reliable. Both reliability and validity can be assessed in several different ways depending on the assessment and the purpose of the assessment. However, it is advisable to examine more than one type of reliability and validity when evaluating child assessments.

RELIGION AND FAMILIES

Religion impacts families by ritualizing spiritual beliefs and rites held by families throughout generations. Families act in ways harmonious with their religious beliefs and principles and transmit religious traditions to their children. Very young children generally follow the religion practiced by their family. As children grow older, they become actively involved in decision making about their religious preferences and ultimate identities. Children's faith background helps define who they are as members of their family, community, and culture.

Religion plays a major role in the lives of families or conversely can have little impact if the family embraces agnosticism or atheism. Religious beliefs can influence, and also are influenced by, families' use of language, cultural and ethnic traditions, and socioeconomic status. Religion may play a minor part of family culture or fully represent or shape culture, transcend culture at a higher level, or conversely be influenced by culture. Religion interacts with culture in influencing parental theological judgments, attendance at religious services, and spiritual goals.

Families are responsible for promulgating the premises of their religious beliefs to their children. Very young children are unable to conceptualize the idea of a higher being or God in a manner similar to adults. Families use traditional stories, myths, and religious documents to help young children learn about the family's religious traditions. Extended and nuclear family members may act as religious liaisons for children in spending time exploring the constructs of the practice through churchgoing and ceremonial events.

Issues of religious discrimination come to the forefront as sectarian religious groups pursue a policy of interference with people's chosen religions. Such actions may cause repercussions inside communities affecting families and young children through many forms such as bullying of children at schools or neighbors stigmatizing others of diverse religious persuasions. Religious restrictions within families, such as enforced gender taboos, extremist family traditions, and sect or cult practices impact societal perceptions of religions.

Research

Research suggests that families who regularly attend church and discuss religious issues within the family circle have children who have better self-control, social skills, and learning approaches than those who do not. Religion can be supportive; through networking, children are reinforced by pro-family messages through other families' voices. This same research indicates that children are more likely to have personal challenges when their parents argue in front of them about religion.

Familial religious beliefs that tend to reinforce blind adherence to tenets of the faith and emphasize control of children act as a severe rather than subtle force in encouraging children to follow rules. Religion and spirituality can be instrumental in the lives of youth and families.

The American Academy of Child and Adolescent Psychiatry posits religion and spirituality can serve as sources of coping and strength during times of stress, trauma, and illness. Religion is a bedrock for the moral and social development of children. Families are served by religious institutions offering community agency support for children and families, such as child care, family shelters, food pantries, after-school recreation programs, and emergency aid.

Families, Religion, and Education

The First Amendment of the Constitution of the United States has been interpreted to mean that “public schools may not inculcate nor inhibit religion” (The Institute for Communitarian Policy Studies at The George Washington University, n.d.). They must be places where religion and religious conviction are treated with fairness and respect. Public schools uphold the First Amendment when they protect the religious liberty rights of students of all faiths or none. Culturally supportive family involvement practices include respecting all families’ religious beliefs and allowing children to share those freely in the classroom.

The issue of religious beliefs surfaces around holidays. In the United States, the school calendar is built around the holidays celebrated in the Christian religion. Schools plan their curriculum around the dominant culture themes, and the classroom read-aloud often features holiday stories from an Anglo-Saxon perspective. This ethnocentric, monocultural emphasis can lead to cultural discontinuity for students from different religious backgrounds, where they feel disconnected from the overall classroom cultural environment because of a lack of connectedness with what is being taught.

Schools demonstrate equity when they ensure that the curriculum includes study about all world religions. Diverse religious holidays offer rich opportunities to teach about religion in schools. Teaching about religious holidays is permissible, as opposed to celebrating religious holidays. Students have the right to express their religious views during a class discussion or as a part of a written assignment or activity. Certain units of study, such as religious holidays, may lead to questions and discussions relating to faith or religious beliefs.

Families and teachers can model a respectful attitude toward others’ religious beliefs and withhold judgment concerning these beliefs. It is also worth remembering that young children’s opinions are often based on their families’ values and may be controversial, and that children and their families can be encouraged to discuss these opinions together. In the classroom, discussing different religious holidays or festivals may not only add to students’ academic knowledge about the world but also be a way to explore family and community diversity.

Families act in accordance with their religious standards to promote homogeneity in a closed society. In an open society, religious diversity among families promotes cross-cultural richness in communities and a commitment to examine and embrace differing beliefs.

RESILIENCE IN ADVERSITY

Resilience in adversity refers to the phenomenon that many children achieve positive developmental and educational outcomes despite experiencing stressful, high-risk, and adverse circumstances in their lives. Early adversity includes experiencing risk factors such as child abuse or neglect, homelessness, poverty, or even premature birth that are associated with serious social, emotional, health, or school-related problems. Developmental research provides evidence for the positive influence of protective factors that promote resilience for children in the face of early risks. This entry provides information about early risk and protective factors from a bioecological systems perspective and suggests opportunities within early childhood educational contexts to promote positive development for children experiencing adversity.

Overview

Why do some children growing up in the context of risk and adversity, such as living in poverty, end up thriving socially and academically, whereas others do not? What protects children who experience these early risks from negative outcomes, such as aggressive problem behavior or school failure? What are factors related to individual differences within children and their environments that promote positive outcomes? Children who display positive development and adaptation despite experiencing adversity are described as *resilient children*.

Ecological Theoretical Framework for Understanding Resilience

According to Urie Bronfenbrenner's bioecological theoretical framework, several nested environmental contexts influence children's development. These range from proximal *microsystem* contexts (those closest to and most directly affecting the child, such as the family, school, and neighborhood) to more distal contexts such as the *macrosystem* and *exosystem* that encompass broader societal influences such as sociopolitical, legal, cultural, and economic conditions surrounding the child, family, and community. The processes through which systems influence children are seen as bidirectional over time. Not only are children influenced by the environment, but the environment is responsive to individual child-level *ontogenetic* (biological or developmental) characteristics as well. Multiple risk and protective factors may influence children's development in the context of adversity.

Research

There is a large body of research documenting the negative effects of risk factors, at each level of the ecological model, on children's development. In addition, research identifies several strengths within the child, family, school, and community that can promote resilience for children who experience such risks and early adversity.

Broader Contextual Risks

There are several contextual risk factors, the most pervasive being poverty. Poverty is associated with several stressors including increased risk for child abuse and neglect, food insufficiency, lack of access to adequate medical care, stable housing, safe neighborhoods, and other community resources known to promote positive outcomes. Experiencing poverty and related risks is associated with several negative outcomes such as delinquency, aggressive and antisocial behavior, low academic achievement, limited cognitive skills, and high dropout rates.

Living in poverty also exposes children to living in underresourced neighborhoods in which there is high unemployment, violence and crime, and restricted access to community resources such as libraries, high-quality schools, supermarkets, and safe playgrounds. Also, children are more likely to attend underresourced schools with limited opportunities for success and advancement, and this may result in high rates of underachievement and dropout. Finally, ethnic minority children, who are disproportionately at risk for living in poverty, also are likely to experience racial discrimination or injustice, which may affect negatively their self-esteem and social-emotional development.

Family Risks

Several familial conditions exacerbate the risk for children to develop serious academic and social-emotional difficulties. Research has emphasized child abuse and neglect, interparental conflict, parental psychopathology, and harsh parenting as risk factors in the family context. Experiencing child abuse or neglect is associated with increased risk for delinquent behavior and conflictual peer relationships. Conflict between parents has been associated with children's psychological difficulties, conflicts at school with teachers and peers, and aggressive behavior. Parent mental health problems, such as depression or substance abuse, and harsh parenting have been linked to children's psychosocial difficulties, including externalizing and internalizing problem behavior.

Contexts and Processes That Foster Resilience

Bronfenbrenner's bioecological model suggests that there are multiple processes that can support positive developmental outcomes for children who experience the risks noted earlier. This theory suggests that early contexts, especially those closest to the child (such as the family and school), are important opportunities for early identification and intervention, to support resilience during the early childhood developmental period. *These positive*

influences can be enhanced to foster developmental strengths within the child. All children are born "ready to learn" and despite living in adverse circumstances may thrive when provided with positive, protective experiences in their home, school, and community contexts.

Individual Within-Child Strengths as Protective Influences

Research has identified several individual *within-child* level factors, such as temperament, self-regulation, cognitive abilities, and self-esteem, that are protective for children and promote their resilience in the face of adversity. An adaptable and approachful temperament is associated with more positive outcomes than less adaptable temperamental styles. A child who displays this temperamental style is described as confident, sociable, attentive, cheerful, adaptable to change, and approaching new situations and others in a positive way. Children with this temperamental style are less likely to develop behavior problems, more likely to develop positive social interactions with peers and teachers, and more likely to succeed in school.

Another factor related to temperament is *self-regulation*, which is defined as children's ability to regulate their emotions, attention, and behavior. Children who have high self-regulation skills display higher engagement in school, motivation to learn, and social competence and lower problem behavior. Children's cognitive ability (or intelligence) is also associated with resilience. Higher cognitive ability predicts academic achievement, can increase self-esteem and self-efficacy in school, and in turn results in lower antisocial and conduct behavior problems. Cognitive ability also may be associated with more sophisticated problem-solving skills, which would help children deal more effectively with stressful situations. Self-esteem and self-efficacy also promote self-confidence and are associated with secure relationships and school success. Research has shown that success in one setting can increase a child's self-esteem and feelings of self-efficacy, which in turn increases motivation to do well in

other settings. This also promotes adaptation and coping skills, as well as higher social acceptance.

Family Strengths as Protective Influences

Several aspects of the family and parenting environment promote resilience, such as a positive parent–child relationship, family engagement in children’s education, and family pride in ethnic identity. Positive parent–child relationships such as playful interactions, and emotionally sensitive, contingent responses to children’s needs, help children feel secure and promote more consistent supervision and discipline.

High parental engagement in children’s learning and education has been found to mitigate the effect of stressful life events and promote resiliency, especially for children living in poverty. *Parental engagement* is defined as the participation of parents in regular, two-way, and meaningful communication involving children’s academic learning and other social activities. When parents engage in educational activities with their children, such as reviewing the names and sounds of letters at home or visiting educational places such as the zoo and library, children show higher kindergarten readiness skills. For children of ethnic minority backgrounds living in poverty, a strong ethnic identity also has been found to promote resilience since it is associated with positive peer and familial relationships and higher self-esteem.

School and Classroom Protective Influences

School is the primary context in which children spend their time (outside of their family). Interactions with key individuals such as teachers and peers within schools play an important role in fostering resilience. Positive teacher–child relationships are one of the most critical protective factors that can support children’s motivation to learn, emotion regulation, social-emotional skills, and establishment of positive peer relationships. Having social support from a teacher gives students more emotional resources to promote healthy social-emotional development and positive attitudes toward school; in turn, with greater social, emotional, and

positive approaches to learning, children are more likely to be engaged in school and succeed, buffered against stressful life events.

Positive peer interactions are also important protective factors and have been associated with early learning in academics (especially language development, creativity, and imagination) as well as increases in social skills. As naturally occurring opportunities, playful interactions with peers, in the home and early childhood classroom, provide opportunities to support “resilient learners” and “peer leaders.”

Community Protective Influences

The neighborhood context may serve as a protective factor for children experiencing adversity by providing extrafamilial social support and connectedness. Neighborhood characteristics such as social cohesion and social control are associated with resilience. Social cohesion refers to the degree to which members of the neighborhood share similar values and beliefs. Social control refers to the degree to which members are likely to take action on behalf of another member’s child. If there is high social cohesion, members of the neighborhood are more willing to monitor and take action on behalf of children in the neighborhood. For example, if a neighbor notices a child is not going to school because he or she does not have consistent or reliable transportation, the neighbor may take action and start picking up and dropping off the child at school. Children living in impoverished neighborhoods with higher social cohesion and higher social control have more positive academic and social outcomes than those in impoverished neighborhoods without these characteristics.

Opportunities to Foster Resilience During Early Childhood

The early childhood developmental period is an optimal time for interventions to promote resilience in adversity. It is important to identify naturally occurring opportunities to foster children’s strengths within home, school, and community

contexts. This strengths-based approach is reflected in the models of several early childhood education and intervention programs. Such programs focus on promoting positive development for children growing up in adversity.

As an exemplar, Head Start is the United States' largest, most comprehensive federally funded program that from its inception has focused on supporting positive development for children and families living in poverty. It adopts a whole-child approach to intervention and provides early childhood education, parent involvement, health services, mental health services, nutrition, and social services to children and their families. In addition, Head Start takes a two-generation approach, focusing on addressing the needs of both parents and children together, to leverage improvements in parents' education and employment opportunities, as agents of positive change in their children's lives.

Other interventions within early childhood programs serving children living in the context of adversity can target important contexts for resilience, such as

- improving the quality of emotionally and instructionally supportive teacher–child interactions to enhance children's school readiness skills (i.e., academic, social, emotional, and behavioral skills). MyTeachingPartner (MTP) is an empirically validated intervention in which teachers work closely one-on-one with a coach to improve the quality of their interactions with children in the classroom. Findings from studies evaluating MTP show that children show greater gains on language and literacy skills and a reduction in problem behavior.
- providing a safe and supportive context in preschool classrooms to encourage interactive peer play for children displaying social isolation due to maltreatment by pairing them with resilient peer “play buddies.” One such program is Resilient Peer Treatment. A study by John Fantuzzo and Patricia Manz found that socially isolated Head Start children, when paired with a resilient “play buddy” in a safe play environment

in the classroom, showed gains in interactive peer play and a reduction in solitary play at the end of the intervention.

- providing support and coaching to parents to improve the quality of parent–child relationships and family involvement in children's education.

RESOURCES FOR INFANT EDUCARERS

Resources for Infant Educators, often referred to by its acronym, RIE, is a not-for-profit organization founded in 1978 in Los Angeles by infant specialist Magda Gerber and Tom Forrest, a pediatric neurologist in Palo Alto, California. The goal of RIE is to help raise authentic infants who are competent, focused, peaceful, involved, cheerful, cooperative, resourceful, initiating, confident, aware, secure, attentive, curious, exploring, interested, and inner-directed.

Gerber and Forrest had been working together since 1972 as codirectors of the Demonstration Infant Program (DIP), a preventive infant mental health program at the Children's Health Council in Palo Alto. Eventually, Gerber and Forrest conceived RIE as an extension of the approach in working with parents and their infants and toddlers that they had developed at DIP, based upon the idea of "selective intervention," with the emphasis on observation and allowing the child to do what he or she could do without help or interference unless absolutely necessary.

Born in Budapest early in the 20th century, Gerber began developing the RIE approach known as *Educaring* (a term she coined) as a friend and colleague of Emmi Pikler, a pediatrician in Budapest, Hungary, who founded a residential nursery for infants whose parents were either dead or unable to care for them, in the aftermath of World War II. Pikler had taken on the task of caring for infants in an institution (now known as the Emmi Pikler Institute, which is still offering training to professionals in the infant/family field) in a way that preserves their ability to connect in a loving way with adults, to value themselves, and to act autonomously with consideration for the needs and wishes of others. This was in sharp contrast to the devastating outcome known as hospitalism, a wasting disease thought to be caused by lack of stimulation, at many other orphanages in Europe after the war.

Gerber first met Pikler when her daughter was sick, was astounded at the respect Pikler showed

the child, and retained her as the family pediatrician. She was gradually drawn in to learn from her and, eventually, to teach and train nurses with her at the institute. The Educaring Approach is an extension and elaboration of Pikler's well-researched ways of fostering movement, cognition, and human connection, combined with Gerber's deeply respectful and progressive method of teaching adults, especially parents and child care professionals. Based also on the constructivist theory of Jean Piaget and John Bowlby's attachment theory, Gerber's method of teaching demonstrated her principles in the way she taught, with an emphasis on authenticity. She felt it was important to give to adults what one wanted them to give to children, most especially in slowing down and allowing them to learn in their own time and in their own way.

During Gerber's lifetime, she had enormous and wide-reaching influence on best practices in infant and toddler care and education through her mentorship of many educators. Among her influential students, colleagues, and proponents are Janet Gonzalez-Mena, who interned with Gerber at DIP and went on to write many child development books, including the widely adopted text *Infants, Toddlers and Caregivers*, now in its ninth edition; and J. Ronald Lally and Peter Mangione, who cofounded WestEd and PITC (Program for Infant/Toddler Care). She taught for 20 years at Pacific Oaks College in Pasadena, California, known worldwide for its progressive approach to early childhood education. Many of her students have gone on to teach at other colleges around the world, and they frequently refer to her work and teachings.

The RIE organization, which has continued to promote Educaring as a highly relevant model in the 21st century even after her death in 2007, offers classes and workshops for anyone wishing to learn the approach, in a number of specified formats. For parent and infants, Gerber developed a unique educational format. The RIE Parent-Infant Guidance Classes offer a two generational setting in which parents have a chance to learn the approach through the demonstration and discussion of the principles by the facilitator, who must

be a fully trained RIE associate. During the weekly classes, the infants or toddlers have the opportunity to move freely, play as they like in a safe yet challenging environment, connect with their parent whenever they wish, and learn to be with other children of like ages, also facilitated by the RIE associate and RIE practicum student/demonstrator.

The basic theory course for adults only is known as RIE Foundations: Theory & Observation, and is open to anyone. The professional training can continue as students may be recommended for the RIE Practicum and from there to the RIE Internship. Students who complete all three levels can join the RIE Alliance of Associates and teach Certified RIE courses, such as Before Baby, Nurturing Nanny, RIE Parent-Infant Guidance Classes, and, for those with additional credentials, RIE Foundations: Theory & Observation. There are RIE associates all across the United States and around the world, and their ranks are growing.

As described in the Educaring Approach section of its website, RIE encourages the following in order to foster quality care (RIE, n.d.):

- Basic trust in the child to be an initiator, an explorer and a self-learner;
- An environment for the child that is physically safe, cognitively challenging and emotionally nurturing;
- Time for uninterrupted play;
- Freedom to explore and interact with other infants;
- Involvement of the child in all care activities to allow the child to become an active participant rather than a passive recipient;
- Sensitive observation of the child in order to understand his or her needs;
- Consistency, clearly defined limits and expectations to develop discipline.

ROUGH AND TUMBLE PLAY

Rough and tumble play is a play style in which children are involved in very physical running, rolling, jumping, chasing and fleeing, tagging, and wrestling that all animal young—including children—do. It is known by many alternate names: roughhousing, play fighting, horseplay. Many of the actions involved in rough and tumble play mimic aggressive actions although the intention of the play is not aggression. Instead, the intention of rough and tumble play is sustained physical engagement between a solitary child or a child and an object, or physical engagement between two or more children, often in a game with rules.

In solitary rough and tumble play, the child uses vigorous physical movements, such as twirling, jumping, rolling, and swinging with arms out wide. A child may also persist in physical challenges such as climbing up a piece of playground equipment or running up a grassy hill. Two children may hold hands and swing each other around in circles, or take turns chasing and tagging each

other, or wrestle. Several children may organize a rough and tumble game with rules, setting boundaries and guidelines about the play. Duck, duck, goose and king of the mountain are such rough and tumble games.

For young children, rough and tumble play is seemingly universal; the first incidences of rough and tumble play were recorded in the 12th century. Rough and tumble play has a determined set of characteristics that—when present—help define the play as rough and tumble. Children typically have a play face, meaning their facial expression is open, smiling, and relaxed. Children are voluntary participants in the play and continue their participation in it willingly. They also sustain the play for as long as possible and return to the rough play again and again. The remainder of this entry discusses the benefits of rough and tumble play, myths and misperceptions about rough and tumble play, and how adults can support rough and tumble play.

Benefits of Rough and Tumble Play

Researchers have determined that every species of every animal studied in every population on Earth engages in rough and tumble play while young. This universal nature of rough and tumble play can be attributed to the myriad benefits ascribed to the play, as rough and tumble play has considerable merit in a young child's overall development. When children engage in rough and tumble play, their physical, social, cognitive, and language development are positively impacted.

Physical Development

The physical benefits rough and tumble play contribute to young children are overt. During this very vigorous play, children are exerting an immense amount of very intense physical energy. Roughhousing is the prime way young children release energy and relax. It is also the prime way young children engage physically with each other and the prime way young children relate physically to each other. While roughhousing, young children are using and further developing their locomotor

and fine motor skills. They are also practicing physical skills that may be required in adult life. Some believe the movements children use in rough and tumble play may be practice for future self-defense, and that the rough play supports development of critical brain pathways required to aid responding to aggression and dominance. The physical contact afforded to young children through rough play also allows them to meet the majority of their physical touch needs and, for young boys, does so in a way that is free of social stigma or bias.

Social Development

The social benefits obtained through rough and tumble play are established as children learn to successfully engage in and sustain play in this play style. Successful rough and tumble play is dependent on the child's ability to signal, detect signals, alternate and change roles, take turns, and reciprocate. As children wrestle, for example, each child must be able to accurately decode what the other child's face and body are communicating so that the wrestling remains within the boundaries of appropriate rough play. Each child must also be able to take turns being the strongest, fastest, or first. And, as rough and tumble play often occurs in groups of two or more children, each child must be able to be second, third, and so on in order for the play to continue peaceably. Through the process of navigating these social skills within the context of rough and tumble play, children are actually honing their individual skill levels, not only increasing their ability for rough play successfully, but also increasing their ability to navigate other social situations that require this same skill set successfully.

As infants, children become aware of their bodies and movements during their rough and tumble interactions with other infants, with a parent or caregiver, and with objects like large rubber balls. Through their physical interactions, these infants begin to understand not only their own bodies and the effects of their body movements, but also the effects of their movements on others' bodies as well. As infants kick, roll, grab, and push each

other, their experiences add to their growing awareness of self and another. This awareness is the beginning of the development of empathy, and it results primarily from the infants' physical interactions with each other.

In the preschool years and beyond, children are dependent on their social skills in turn taking and reciprocity to successfully navigate rough and tumble play episodes. Children who engage in rough and tumble play exhibit strength in these social skills. Conversely, children who do not rough and tumble play well with their peers generally lack the ability to take turns and reciprocate in the play. Rough play is perhaps of more value to these children as rough and tumble play provides the scenarios needed to develop the social skill they lack. Children who roughhouse with each other are generally already friends with each other and they voluntarily choose to participate in the rough play episodes. Children who lack the requisite skills to roughhouse successfully may have difficulty locating rough play partners from among their peers and may require adult assistance in order for their rough play to continue.

Cognitive Development

Rough and tumble play enhances young children's cognitive development as it provides them with opportunities to engage in complex decision making and problem solving. In infancy, children are learning to coordinate their body movements in order to achieve specific outcomes. As infants bang, throw, and grab—other objects or each other—they are exhibiting curiosity, the foundation of cognitive development. Often the rough and tumble play scenarios preschoolers and school-age children organize for themselves require the children to pay attention, plan, organize, sequence, and then make decisions about how the play will progress. As children engage in more and more of these rough and tumble play scenarios, the more likely they are to develop strong problem-solving skills.

Bouts of rough play also aid children's cognitive development as children are better able to pay attention after engaging in this vigorous rough play. Children also demonstrate better academic performance in both reading and mathematics after participating in rough and tumble play. Rough and tumble play also supports the release of chemicals that affect the midbrain, lower forebrain, and cortex. These chemicals positively affect the development of these brain areas, the areas responsible for decision making and for social discrimination. Children who have not had sufficient opportunities to roughhouse demonstrate an inability to adjust their behavior to the idiosyncrasies of a peer's movements.

Language Development

An aspect of cognitive development, language development, is also supported when children rough and tumble play. The dimension of language development that is impacted the most is children's nonverbal language development. When children rough and tumble play with each other, they typically use a variety of signals, gestures, body postures, and facial expressions to communicate with each other what each intends from the play. As children navigate the rough play, they learn how to accurately decode these signals and gestures. They also learn how to understand the enormous amount of information that is communicated through a facial expression or through the tension of a hand or arm. The majority of information adults communicate with each other is nonverbal, and so children are dependent on the opportunities rough and tumble play provides them to practice and perfect their nonverbal language skills.

Myths and Misperceptions

Rough and tumble play is a vital part of a child's overall optimum development; however, there exist several misunderstandings and misperceptions about what rough play is, and what it is not. Rough

and tumble play is not the same as real fighting, although several of the body positions and gestures may appear to be the same as ones used in real fighting. The goal of rough and tumble play is comradery. In rough and tumble play, the child's face is relaxed and smiling; he or she is a willing participant and returns eagerly to continue the play. The goal of fighting is dominance and control. In fighting, the child's face will be tense and, often, the child will be crying. One child will dominate another, and the dominated child will typically try to leave the play episode, usually by running away, and will not willingly return to the play.

The movements that young children use in their rough play can also be misleading if not accurately interpreted by the attending adult. Rough and tumble play is rough, very vigorous, often boisterous, and always physical. The movements children use often mimic aggressive movements. The actions seem aggressive, but they are not. Instead, the children are engaging in a type of pretend aggression just as they pretend and act out in other sociodramatic play scenarios. From a cultural perspective, the amount of pretend aggression in children's rough and tumble actions correlates to the amount of simulated or actual aggression children witness in their own lives and in their own cultures.

Another misperception is that rough and tumble play will become fighting if children are allowed to engage in it. Most children are quite adept at recognizing that play fighting is not real fighting. In fact, children are better at discerning rough and tumble play from real fighting than many adults are. When rough and tumble play does become real fighting, one or more of the children involved lack the skills, especially the skill of turn taking and reciprocity, required to roughhouse successfully. In these instances, adult support and guidance can aid these children while they play so that they can, through the rough and tumble play, have the opportunities needed to develop the very skills they currently lack.

There is also a misperception that boys are the only children who engage in rough and tumble

play. Although boys do roughhouse in greater numbers than girls do, both girls and boys enjoy and willingly participate in rough and tumble play. Boys seem to exhibit boisterous physical actions that more closely mimic actual physical aggression than girls do. Again, this mimicked aggression rarely leads to real aggression. Boys tend to initiate more rough and tumble games, and girls tend to withdraw from rough play at an earlier age than boys do. As boys age, the mentoring opportunities available within rough and tumble play are imperative for them, and this play style provides them ways to express needed intimacy in socially acceptable ways.

Supporting Rough and Tumble Play

Children rough and tumble play with each other without instruction from adults. To support their rough play, though, there are elements adults can provide that support their play and help them engage in and extend their rough and tumble play bouts. Indoor environments should have beveled or rounded edges instead of pointed ones. Area rugs should be skid free. There should be enough space for children to navigate comfortably, and a safety surface should be provided to absorb the shock of falling if children are more than 2 feet off the ground. Outside, children rough and tumble play longer and more productively in natural landscapes with logs, rolling hills, sand pits, and embankment slides than they do in the more typical playground with several pieces of large, fixed play equipment. Expectations of the children's play and policies about how adults can guide and support rough and tumble play are also beneficial for young children. Supervision, too, is key. Supporting rough and tumble play requires supervision of it.

S

SCHOOL OF THE 21ST CENTURY (21C)

The School of the 21st Century (21C) is a model approach to the provision of school-based child care and family support services. Schools implementing the School of the 21st Century address the needs of children and families beginning at the birth of the child, providing home visitation programs; child care for preschool and older students; and a range of health, mental health, and social services. Conceptualized in 1987 by Edward Zigler, it is one of the earliest models to view the school as the focal point in the community and utilize schools to provide both academic and non-academic services.

Overview

There are hundreds of 21C schools across the country; some of them are also known as family resource centers. Hundreds of other schools are implementing similar approaches such as full-service or community schools. Although some programs focus on low-income children who are at high risk for educational failure, 21C is universal, providing services for all children regardless of their socioeconomic background. Its goal is the optimal development of all children, through the provision of child care and family support services.

In its linking of child care and education, 21C has contributed to significant changes within the school, noting that education begins early in life and underscoring the concept of the whole child, that is, that children develop as a whole. All developmental pathways—cognitive, social, emotional, and physical—are essential for optimal growth and development. Moreover, there is interdependence in all aspects of development, and deficits in one area often affect the whole child. A substantial body of research exists that shows that health and social and emotional skills are vital to success in school as well as in life.

Also of significance is the notion underlying 21C that several institutions influence children's development. Urie Bronfenbrenner portrayed his theory of human development showing that children develop within and are influenced by multiple contexts: their own biology, the home, the neighborhood, the school, the media, and the prevalent culture. The ecological approach also includes influential agents such as one's friends, health, and other services that may exist, indicating as well that children not only are influenced by those around them; they themselves influence others and thus, in part, shape their experiences.

Need

During the past several decades, child care has become a major institution affecting children.

Children, often from the first few months of life, are in child care centers or forms of familial or nonfamilial care. Yet, there were no policy provisions to accommodate this societal change. A related change has been the dramatic rise in the number of single-parent households, due to divorce and parents who do not marry. Other changes in family structure have been caused by high mobility, especially in families with young children, and a lack of social capital, which refers to the dearth of adults in the lives of children and weak ties between families and their neighbors and kin. The result has been increased isolation and alienation, with many parents raising children with little help and social support, further exacerbating the need for child care systems.

In addition to these societal changes, a large number of young children live in poverty, and increasing populations of children are from immigrant families. These circumstances create stressful conditions under which many young children are growing up and can have profound developmental and educational consequences.

Implementation

It is against this backdrop that the School of the 21st Century was conceptualized, calling schools to (a) provide services on a continuum, beginning at the birth of the child through the elementary and middle school years; and (b) utilize the school building for the provision of child care and the coordination of various other child and family support services.

21C includes several service components:

- Guidance and support for parents: Recognizing parents' important role in their child's development before they even come to school, 21C schools offer home visits, playgroups, and workshops for parents of infants and toddlers.
- Child care: 21C schools provide all-day, year-round, high-quality child care for children ages 3 to 5, and before- and after-school and vacation care for school-age children.
- Health: In collaboration with community partners, 21C schools offer health, nutrition, and fitness opportunities and physical and dental assessments.
- Training for child care providers: To strengthen the quality of child care, 21C schools provide regular staff trainings and invite others in the community.
- Information and referral: 21C schools inform families about a wide range of services that are available in the community.
- Mental health: Programs are implemented to ensure positive school climate and enhance children's social and emotional competence and coping skills.

Guiding Principles

Differences exist among schools and communities in the need for 21C services noted above as well as the resources available for implementation. Hence, not all 21C service components will be implemented in all schools. Additionally, schools often undertake a phase-in approach and prioritize implementation, beginning with some services and later adding to these.

This flexibility in implementation has enabled schools to address demographic and other changes that occur over time and has contributed to the success and sustainability of 21C. It has meant that there are variations among 21C schools in the constellation of services provided. However, all 21C schools share the same goal: the optimal development of all children. Also, they uphold the 21C guiding principles, which are as follows:

1. Strong parental support and involvement
2. Universal access to child care, achieved through sliding scale fees
3. Programmatic focus on physical, social, emotional, and intellectual development of children
4. High-quality programming that is developmentally appropriate and measured by staff qualifications and staff-child ratios, group size, staff turnover, and other relevant criteria

5. Professional training and advancement opportunities for child care providers
6. Noncompulsory programming utilized at the discretion of the family

SCHOOL READINESS

The concept of school readiness has been defined and redefined over the years. School readiness refers to the developmental status of children at the time of school entry (i.e., kindergarten) with an emphasis on skills and dispositions that affect later academic success in school. A common thread in definitions of school readiness is that it is multidimensional, including a shared focus on cognitive/preacademic, communication, and social-emotional learning.

Efforts to address school readiness are longstanding. Head Start was founded in 1965 with the hope that early intervention could provide children living in high poverty the “head start” they needed to be successful in kindergarten. While the original design of that early intervention did not have intended outcomes, decades of research confirm that the path to children’s success in public school

begins long before kindergarten. A study by Betty Hart and Todd Risley conducted in 1995 showed that by age 4, children growing up in high-poverty families heard 32 million fewer words than children in professional families, a finding with important implications for later literacy learning.

It is widely accepted that children’s earliest learning happens within their relationships with key adults. With more than 12 million children under age 5 spending at least part of the time in nonparental care, the potential for early childhood care and education programs to mitigate gaps in school readiness is recognized as a strategy to support school success. The National Institute for Early Education Research (NIEER) reports that prekindergarten programs, some universal and some targeted, continue to expand as states seek to raise and maintain student achievement and hold schools accountable for children’s learning. State-funded prekindergarten programs have become a primary strategy for addressing income and racial disparities in school achievement. Research linking children’s participation in early childhood programs to higher academic and social readiness for school shows that higher quality programs lead to greater gains, especially for children growing up in poverty.

This entry briefly traces the historical and political context of school readiness, discusses the characteristics of effective programs and features of programs, summarizes research, and indicates future directions for this important topic.

Historical and Political Context

Two types of readiness coexist and overlap in discussions of readiness and policies affecting it. One type of readiness refers to a child’s developmental growth sufficient for him or her to benefit from schooling. Issues of health, self-care, and emotional and social skills combine with some degree of academic skill. Historically, the belief that maturation was the primary consideration for a child to be successful in kindergarten led to the practice of routinely screening children out of kindergarten. The intent of the practice was to protect the

child from a curriculum deemed too difficult. However, children held back from kindergarten did not benefit from this practice in terms of later school achievement, and many of the most vulnerable children were hurt by it since they missed out on a year of education at age 5.

The second type of readiness evident in discussions of the topic defines readiness as a specific set of academic skills aligned to the kindergarten curriculum and common state standards for children completing prekindergarten programs. This shift in thinking and in public policy gave rise to Goals 2000: Educate America Act, Pub. L. 103-227, in 1994 where the onus for readiness was shared by the school, family, and community. Schools were encouraged to be ready for children and to provide the supports necessary for communities and families to prepare children adequately. The goal was having all children “ready to learn” by the year 2000. A focus on transition to school included practices such as timely records transfer, orientations for children and families, and regular conversations between kindergarten and preschool teachers. However, the impacts of these practices on later school achievement were not systematically examined. Goals 2000 became the precursor to No Child Left Behind in 2001 and assumed that all children could learn. It mandated measurable improvement in student achievement to demonstrate how schools were responding to the challenge of supporting readiness. The onus for readiness shifted more to teachers, schools, and accountability measures and less on children’s entering skill level. The mechanisms by which teachers and schools support school readiness is the current focus of attention, as accountability for school readiness is shared between early care and education programs and public schools.

Skills Associated With School Readiness

Since the enactment of the No Child Left Behind Act in 2002 and the growth of state accountability systems, early childhood program curricula and assessment have emphasized assessing early literacy and math skills. It is not surprising to learn

that children entering kindergarten with specific early reading skills such as naming letters, phonological ability, beginning sound-letter knowledge, and expressive and receptive language show higher early literacy scores when tested later. Similarly, proficiency in early numeracy skills, especially in counting and number sense, is correlated with later math achievement. Catherine Scott-Little, Sharon Lynn Kagan, and Victoria Frelow conducted a content analysis of 46 early learning standards in 2005 and found that more frequent emphasis was given to language and cognitive domains than to physical development, reading comprehension, and social-emotional learning. They also found that standards developed under state departments of education emphasized social and emotional learning less often than standards developed by other agencies such as Head Start and those who regulate child care.

Professionals and researchers in the early childhood field point to the importance of social-emotional learning to later school success. Harder to measure and less likely to be tracked into elementary school are outcomes associated with social-emotional learning and play. Both are less well documented in the school readiness literature despite being named as important by parents and teachers. It is documented that 5-year-olds with poor self-regulation skills, known to be related to emotional learning and play, are likely to encounter socioemotional and academic difficulty in fifth grade.

Characteristics of Effective Prekindergarten Programs

There is general consensus that high-quality prekindergarten programs can support children’s school success. However, research conducted by Robert Pianta, Martha Cox, and Kyle Snow (2007) suggests that most settings fall short of meeting the conditions known to support school success. If we are to better understand why achievement gaps persist in spite of the expansion of prekindergarten programs, it is important to understand the characteristics of those programs.

In 2010, Diane Early and a team of researchers reported the results of an 11-state study examining how children spent time in preschool. Analysis showed that the prekindergarten day was divided among free choice, teacher-assigned activities, routines, and meals. Children spent much of their time in language/literacy, social studies, and art, and less time in math and gross motor activities. Of concern was the observation that up to 44% of the entire day and 88% of routine time was spent in “no coded learning activity.” It was also noted that classrooms with children from more affluent families, with lower proportions of racial minorities, were generally engaged in richer and more stimulating experiences. Other studies reported high levels of non-goal-directed activity in preschool settings. An earlier study led by Early and colleagues using the National Center for Early Development and Learning’s multistate data found children interacting with adults only 27% of the time they are in programs, another indication of the lack of productive time.

Attention has turned to the role of the teacher in structuring experiences that foster and sustain academic and social growth. A 2007 study by a team of national researchers, Jennifer LoCasale-Crouch and colleagues, found only 15% of classrooms to be of high quality in both emotional and instructional support, while in 19% of classrooms, the levels were at least one standard deviation below the mean. Another study, led by Carollee Howes in 2008, found that children showed larger gains in academic outcomes when they experienced higher quality interaction or closer teacher–child relationships. Gains were not related to characteristics of the child or the program (e.g., program location or length, adult–child ratio, or teacher qualifications). Increasing teachers’ academic and emotional responsiveness to children is a structural improvement that may be relatively easy to measure and support.

Building on his own work and that of colleagues conducting national studies over 2 decades, Pianta and colleagues have identified three domains with strong empirical and theoretical foundations used to measure classroom quality: emotional support,

classroom organization, and instructional support. This group of researchers developed a valid and reliable classroom observational tool called the Classroom Assessment Scoring System (CLASS) to measure teacher–child interaction. Indicators rate quality at the classroom, not individual child level. Research reported by the Office of Head Start in 2012 (Halle, Hair, Wandner, & Chien) that used the CLASS tool and followed up on children’s outcomes in elementary school suggests thresholds of quality in the ways teachers interact with children and organize programs. Classrooms need high levels of emotional and organizational support (scoring 5 or better on the CLASS 7-point scale) to promote positive social behavior and reduce challenging behavior. The threshold for protecting children’s academic achievement was much lower with a score of 3, though higher in the instructional support domain associated with improved academic outcomes for children. More than a third of Head Start programs assessed in the 2010–2011 monitoring report fell below the threshold for the instructional support domain.

Bridget Hamre, Pianta, and others have worked to better understand how teachers improve the outcomes of elementary school children both by structuring learning environments and by their interactions with the children. The concept of *responsive teacher* embodies skills that support academic as well as social learning. Responsive teachers are highly engaged with children, attuned to the needs and cues of individuals and groups. They are intentional in what and how they teach, promoting language and concept learning, and able to quickly intercede when a child loses focus. In her 2014 review of teachers’ interactions with children, Hamre pointed to the importance of daily, intentional interactions. While acknowledging the value of the CLASS in broadly measuring emotional climate, organization of the learning environment, and instructional support, it does not focus on individual children’s experience in classrooms. It assesses the frequency and quality of teacher feedback but does not address the content taught. Indeed, very few programs use evidence-based, developmentally appropriate curricula.

Classroom quality as measured by teacher–child interaction appears to be a strong predictor of school readiness. A responsive teacher is one who creates a safe and engaging environment and who focuses children’s attention on language and concept learning. Pianta and colleagues have helped define the contexts in which children best learn. Other work examines the content (or curriculum) elements related to later school success.

Developmentally Appropriate Practice and School Readiness

As the accepted definition of developmentally appropriate practice (DAP) changes to include direct instruction and assessment, the role of the teacher has shifted from one whose focus is on promoting children’s interaction with peers and materials to one who also scaffolds language, concept learning, and content-specific skills. The initial position statement on developmentally appropriate practice developed by the National Association for the Education of Young Children was heavily influenced by Piagetian ideas of learning and so, not surprisingly, emphasized teachers’ roles in providing challenging materials for children to explore and manipulate. The ideal was for children to spend relatively little time in direct instruction and more in child-initiated play experiences. The revised position statement from 2009 reflects understanding from research in child development and knowledge of educational effectiveness. It supports children’s learning through intentional teaching in all domains, including, but not restricted to, early literacy, math, and cognitive development. The role of teacher is paramount in this broadened definition of DAP.

Programs that score poorly on the measures of classroom quality may be adversely affected by some teachers’ adherence to a more child-centered philosophy and their reluctance to provide instruction with a specified scope and sequence. Some researchers suggest that teachers’ beliefs in traditional definitions of DAP might inhibit their

willingness to embed instructional support into their teaching practice. Policies that guide teaching may be at odds with what teachers and parents deem important.

A new case study of Head Start teachers suggests a possible “new normal” emerging in thinking about developmentally appropriate practice. In Allyson Dean’s (2015) recent dissertation research, the teachers in her study rely on assessment data of children and their own CLASS scores to inform their teaching practices. The children’s progress provides the mastery experiences necessary to support the teachers’ own efficacy and commitment to their own professional development. As teachers improve, children improve; as children improve, teachers improve.

As shown above, teachers’ beliefs about the role of prekindergarten and the skills necessary to demonstrate readiness are changing. Parents’ views are also changing. As public and private prekindergarten programs become more available, parents become more aware of the role of programs in promoting readiness. Beth Hatcher and colleagues conducted two studies about parents’ and teachers’ views on school readiness in 2006 and 2012. Earlier views supported a range of comparable studies in showing that teachers valued social and communication skills related to participating in a school program higher than academic skills but that parents more likely linked academic skills to school readiness. In 2012, however, parents and teachers held shared perceptions of readiness including the range of social and emotional development, the attainment of literacy skills, and comfort with school routines.

Conclusion and Future Directions for Readiness Conversations

Not since the beginning of Head Start has so much public money been spent on preschool education with a goal of ensuring school success for all children. Great strides have been made in identifying the classroom conditions linked to achievement gains, in professional development for teachers, and in creating systems to monitor

children's progress. Policy statements by both early care and education and public school organizations acknowledge the importance of relationships and classroom environment in promoting learning as well as embedding academic skills and content knowledge in developmentally appropriate curricula. Strides have been made to close the achievement gap related to the affluence of families and the language spoken at home. Gaps still persist, especially in the area of instructional support. Children of color and in lower income areas continue to attend programs of lower quality and are exposed to teaching practices that fail to create the foundation for the increased conceptual learning that will occur later in schooling. The need to systematically understand better the effects and outcomes of different preschool curricula and the role of play on both long-term and shorter term achievement continues.

While classroom-based teaching interventions are helpful, the need to link practices to individual children's outcomes and build upon the strengths that both early childhood education and K–12 education bring about with effective transitions is a necessary next step. Advocates urge that not only teachers and parents but also communities bear responsibility for school readiness. Issues such as food scarcity, housing instability, community violence, and mental health support affect children's readiness to benefit from effective schooling experiences. As such, collaboration among schools and community agencies must be supported in efforts to increase children's achievement.

SCIENCE

Science refers to a system for acquiring knowledge, through observation, experimentation, and organization of information, a system that results in general principles and laws that describe and explain how the world works. Young children are constantly engaged in building theories about the world around them, and early childhood education can support and nurture this theory building. This entry discusses elements of science and how this relates to early childhood education, focusing on curriculum, the role of the teacher, and the role of the environment.

What Is Science?

We can think about science in terms of what we understand (content) and how we come to understand it (methods). In a very general sense of the word *science*, we are talking about learning about anything that is out there in the world.

Content of Science

The general principles and laws that describe and explain how the world works can be categorized by the focus of the study—geology, for example, refers to the study of the Earth, botany to the study of plants. We can think of the knowledge as specific in nature—vocabulary particular to the science, for example, or as conceptual—the big ideas studied by the science, big ideas that may integrate knowledge across disciplines. Young children are engaged in constructing physical and logico-mathematical knowledge (conceptual knowledge) through interactions with objects, materials, and people and can acquire social knowledge (vocabulary) in meaningful contexts.

Methods of Science

The scientific method refers to how we collect and interpret information about the world in a systematic way that can be called *theory building*, according to Christine Chaillé and Lory Britain (2003). The process of theory building includes the following elements: making predictions, formulating hypotheses, testing the hypotheses, observing the result of the testing, and verifying or modifying the theory based on this process. While some of what young children engage in may not appear to be clearly involving the scientific method, these elements are seen throughout their learning.

Views of Science in Early Childhood Education

Many in the field of early childhood education would contend that science is not given sufficient emphasis. This is based in part on the belief among many teachers that science is too abstract or conceptual for young children, as well as the

belief that teaching science requires a scientific background that many teachers in the field do not have. The lack of content knowledge among early childhood professionals, combined with a lack of understanding of science, often results in limited exposure to science education in the early years.

The exception to this involves the incorporation of animals and plants in the early childhood classroom. The study of living things is historically one curricular area that early childhood teachers have embraced. A broader base of scientific inquiry and exploration beyond biology, however, has been lacking. The position statement on early childhood science education of the National Science Teachers Association (also endorsed by the National Association for the Education of Young Children) articulates the need for such support.

Young Children as Scientific Thinkers

There is strong evidence that young children are capable of learning core ideas in science and constructing conceptual understanding in the early years, capabilities that are sometimes underestimated, according to the National Research Council. Young children's ability to engage in sustained exploration and experimentation has also been, at times, devalued; there is ample evidence that young children are capable of extended and focused work when given the opportunity and time. A number of early childhood science educators contend that young children are naturally engaged in scientific thinking. From the standpoint of Jean Piaget's theory of learning, young children are engaged from birth in constructing schemas and theories, and then applying their theories to the world around them. If we change our view of science to be what young children are naturally engaged in, then science is demystified and accessible, both to young children and to early childhood teachers.

Supporting Scientific Thinking in Young Children

There are many ways to support scientific thinking in young children, including thinking about

the role of the teacher, the role of the environment, and the role of the curriculum.

Role of the Teacher

A teacher who is interested, curious, and engaged in science provides an important model for young children. Part of this modeling is to engage in exploration of ideas, concepts, and topics that a child genuinely doesn't understand, demonstrating an authentic quest for understanding. Asking questions is key here, and modeling the tools and strategies for finding answers to questions—through experimentation, observation, or the use of resources—is an important role the teacher can play. Teachers should not be the source of information but, rather, the facilitators of children engaged in searching for answers to their own questions. This stance of the teacher as a colearner with children empowers them to construct their own theories rather than to look to the outside for answers. The image of the teacher as expert changes, which also frees the early childhood teacher who may feel uncertain about his or her own knowledge base to learn alongside children.

Teachers also serve as facilitators when children encounter interesting questions, capitalizing on the moment when, for example, the spider begins to molt, or when glasses in the window cast colorful spectra on the wall of the classroom. The teacher can also provoke such interests by purposely placing different lenses in the window for children to encounter, or by provoking interest in movement by showing a video of objects being blown by the wind.

Teachers also play an important role in providing language tools as children engage in exploration and experimentation. Although learning vocabulary should not be the primary goal of early childhood science education, teachers can authentically use scientific vocabulary in meaningful contexts. For example, when children are engaged in constructing marble rollways, discussing how the marble goes faster on a steeper incline, the teacher can use the words *velocity*, *incline*, and *force* in discussing the children's experimentation.

Role of the Environment

The environment also plays an important role in supporting young children's scientific thinking. In terms of the physical space, having opportunities in the classroom, as well as outside the classroom, for engaging in projects that may take up space and that may need to extend over time can support focused experimentation and exploration. Opportunities to engage in play outside, on a playground, or in nearby natural spaces are also desirable.

Materials and objects that are accessible to children and that can be used in multiple ways also support experimentation and exploration. Such supplies include construction materials, loose objects and manipulatives, and interesting materials, in addition to scientific "tools" used for particular explorations (e.g., observation tools such as magnifiers of different kinds). Supporting young children's scientific thinking does not take expensive and specialized tools, but can be fostered by any materials that provide opportunities for experimentation, many that are readily available in any classroom.

Role of the Curriculum

Different curriculum models provide different approaches to science education. The more teacher-directed traditional model provides structured lessons that often include demonstrations and specified actions on the part of children. Constructivist approaches, on the other hand, provide guidelines for teachers to prepare materials, provocations, and opportunities for children to engage in theory building, according to Nancy A. Branscombe and colleagues. Constructivist approaches also encourage the combination of careful planning of such experiences with the flexibility that allows for teachers to pay close attention to questions that capture children's attention and engagement. Some constructivist curriculum approaches are explicitly aligned with standards. If they are not, it is not difficult to see the connections with standards specified for young children and the kinds of constructivist explorations that would support children's scientific thinking.

Curriculum integration lends itself well to the incorporation of scientific thinking as a focus, since the big ideas underlying science can generate activities and experiences across the curriculum. Curriculum integration can encourage children's scientific thinking in all aspects of life, an important goal for early childhood educators.

In sum, early childhood educators can help to support children's scientific thinking, providing a strong foundation for later science learning as well as supporting inquiry, questioning, and curiosity throughout the curriculum.

SELECTION OF FURNITURE

For an early childhood school and classroom space, furniture selection involves thinking about

the uses of space and planning for both more permanent as well as flexible places. For example, wet, dry, active, quiet, public, and private classroom zones may help define a space based on conceptual ideas such as a high drama, puppets, and large books; building materials; and climbing lofts and other more open floor spaces, where sparsely arranged furnishings made from hardwood and low shelves may be more appropriate. Entrance and exit zones where personal effects are stored, studio spaces, eating, woodworking, exploratorium, and take-apart spaces may necessitate more lasting storage shelves, tabletops, counters, and cupboards above sinks, acrylic tactile tubs, and so on. Such larger allocated zones may help to determine the types of furnishings utilized in an overall design plan.

Furniture can include new, handcrafted, and reused materials. While some new early childhood specific furnishings can offer a higher standard for durability, protections such as rounded corners (rather than sharp edges), long-lasting cleanable surfaces, and lightweight maneuverability, older custom-made and/or reused materials can offer a homelike quality and variation in architectural style and design as well as awaken whimsy, wonder, and imagination.

Further, mindful furniture selections can recall utilitarian and single-use options (i.e., always the recycling tubs and shelves area; labeled and distinctive) or variable-use and imaginative dreamscapes (i.e., can build forts or a castle or be a water play dreamland). Furniture defines flexible and/or static space into thoughtful places for young children and their families.

Designing spaces with chosen types of furnishings requires thinking about principles, values, ideals, and philosophies emitted from the space. Situating tables and chairs of varying styles and shapes invites different-size groups to enter, work, stay involved, move about, collaborate on ideas and projects, and work alone and so on. Hanging furnishings such as bulletin boards near active spaces allows for photos, narratives, and captured learning experiences to evoke memories and give credence to the learning designs and furniture style

and placement. Further, other types of hanging furnishings such as floating shelves, spice racks, bracketed ledges, and reflective surfaces allow for collections of materials, moveable picture frames, specialized materials brought down during specific moments, and so forth.

Another important consideration in selection of furnishings is size and scale. Furnishings chosen to typical children's scale invite different participation than average adult-height table and chair sets. Scaling the majority of furnishings to the everyday inhabitants is crucial for ease, comfort, and opportune learning environments. If a storage unit scales much higher than a child can reach, then offering furniture helpers such as step stools or stepladders may be desirable. A mixture of adult- and child-size furnishings is often required as teachers, parents, and other adults necessitate seating, storage, and other furnishing accommodations, as do the children. Seeking to meet the furniture needs of all community participants welcomes everyone in the classrooms and school environment and prioritizes inclusion philosophies directly in the furniture planning.

Often, color choices and styles of furniture are a valuable consideration. If the furnishings are more monochromatic (all in the same color family), then the materials stored in them may stand out visually. If a polychromatic color scheme (multiple color spectrums) is chosen for furnishings, then the room layout becomes the visible marker for the space and the stored materials and inhabitants may fall to the background. As well, the style of furnishings gives shape to the overall aesthetic and this quality speaks to the inhabitants and defines uses. As an example, if a deep shelf is selected for materials storage, then materials can be sorted more horizontally. As children select materials along a horizontal plane (imagine reaching across), they develop a relationship with the material layout in depth. Or if a tall narrow shelving unit is used to store materials (imagine reaching up or crouching down), the layout, visual cues, and material selections made offer a different process of choice making and the material layout speaks to the children differently. Thus, children come to and address the

materials differently based on the type of furniture selected.

Additional qualities to consider in furniture selection include the elements chosen that make up the furniture such as wood, metal, plastic, textiles, ceramics, and other properties. A nook with a metal bench, plastic seats, and wooden shelves suggests a different play and learning place than does a soft-pillow couch behind a hardwood square low table with pullout drawers for materials. Offering diverse tactile familiarity allows for variation in learning experiences based on the values produced from furniture selection and arrangement.

In any case, the materials selected must be cleanable, protected from easy scratches, dings, and damages. If wood surfaces are chosen, they must be veneered or safeguarded in a way to prevent lasting damage such as bacteria or blood spills from soaking into the wood permanently. Maintaining a balance between aesthetic forms and practical functions assists in aligning the teaching philosophy and everyday living experiences. As an example, placing stacking chairs next to a learning space invites a philosophy of extra participation in an activity when unstacked and used as well as allows for more open space when stacked up and put aside as desired. Form and function come together to open and shape schools and classrooms for learning and living.

Overall, selecting furniture informs and codetermines the experiences inside classrooms and schools for young children, their families, teachers, and community participants. Furniture selection and attention to details about furniture augments the learning and living atmosphere of a space and turns classrooms and schools into more mindful places of learning.

SELF-REGULATION

Self-regulation has been established as an important foundational skill associated with a variety of outcomes, including school readiness, academic achievement, and long-term health and educational outcomes (McClelland, Acock, Piccinin, Rhea, & Stallings, 2013; Moffitt et al., 2011). Although researchers have described self-regulation from a diverse set of perspectives, experts agree that self-regulation has important implications for health and well-being starting early in life. Self-regulation includes both top-down (executive functions, or EF) and bottom-up regulation of thoughts, feelings, and behavior (Blair & Raver, 2012). This entry focuses on the cognitive aspects of self-regulation that are rooted in self-regulation processes including attentional or cognitive flexibility, working memory, and inhibitory control.

Attentional or cognitive flexibility allows children to shift focus and pay attention to new details. Working memory allows children to remember and follow directions and helps them to plan solutions to problems, and inhibitory control helps children stop one behavior in favor of a more adaptive positive behavior. Integrating multiple aspects of self-regulation allows children to control their behavior, remember instructions, pay attention, and complete tasks in classroom settings. Moreover, this integration is important for successfully navigating early learning environments.

The Importance of Self-Regulation for School Success

A large body of research demonstrates that self-regulation significantly predicts achievement and social outcomes prior to formal schooling, throughout elementary school, and into adulthood. In contrast, children who struggle with behaviors, such as talking out of turn and failing to complete assignments, have more difficulty in classroom settings. In many studies, self-regulation significantly predicts achievement even after controlling for initial achievement levels and other background variables such as child IQ, age, ethnicity, and parent education level. In a 2013 study, a child with one standard deviation higher teacher ratings of attention and persistence at age 4 had 49% higher odds of completing college by age 25 than a child at the mean of these variables (McClelland et al., 2013). Moreover, recent evidence suggests that self-regulation is malleable and is shaped by the context in which a child lives (Schmitt, McClelland, Tominey, & Acock, 2015). Thus, promoting strong self-regulation in young children has been the focus of increasing research in recent years.

Influences on Self-Regulation

The Role of Sociodemographic Factors and Self-Regulation in Early Development

Children's self-regulation skills vary based on a number of sociodemographic factors, which include socioeconomic status, parent education level, identifying as an ethnic minority, and being an English language learner (ELL). Low socioeconomic status is related to low self-regulation on a variety of measures (e.g., caregiver report, direct assessments) and may indicate children's responses to chronic stress or to being exposed to fewer optimal learning experiences. Parent education has been documented as a key influence of children's development including self-regulation. For example, in one study, lower maternal education was related to lower scores in math, reading, and vocabulary for young children (Sektan, McClelland, Acock, & Morrison, 2010).

In the United States, ethnic minorities disproportionately experience educational disparities and poverty, according to the U.S. Census Bureau, which can result in difficulties navigating and accessing the resources necessary to promote quality early learning experiences that foster the development of self-regulation (Gándara, Maxwell-Jolly, & Driscoll, 2005; Wanless, McClelland, Tominey, & Acock, 2011). Finally, ELLs are more likely to be low income and have lower self-regulation and lower academic achievement compared with their peers. In one study, ELLs from low-income families began prekindergarten with significantly lower self-regulation and exhibited a slower rate of growth than low-income English-speaking monolingual children through kindergarten (Wanless et al., 2011).

Although sociodemographic risk can have a negative influence on children's early development, there is also evidence that strong self-regulation can serve as a protective factor and help ameliorate the negative influences associated with sociodemographic factors. In the 2010 study by Michaela Sektan, Megan McClelland, Alan Acock, and Frederick Morrison, regardless of the presence of a risk factor, children with stronger self-regulation had significantly greater academic achievement than children with weaker self-regulatory skills. Moreover, for children with the same number of risk factors, those with strong self-regulation performed better academically than children with low self-regulation. Another recent study found similar results with a sample of homeless children. Thus, even when children are exposed to considerable risk, those with stronger self-regulation have better school outcomes than those with weaker self-regulatory skills.

Parenting and Self-Regulation

A number of studies have established the essential role that parents play in the development and growth of children's self-regulation. Parenting behaviors and skills such as positive parent-child interactions, parent support and warmth, and high-quality home learning environments can

promote children's self-regulation (Bernier, Carlson, & Whipple, 2010). For example, in one study, mothers who were responsive and used lower rates of physical punishment were more likely to have children with high levels of self-regulation in middle childhood (Colman, Hardy, Albert, Raffaelli, & Crockett, 2006). Although research suggests that children experiencing multiple sociodemographic risk factors may have difficulty in academic settings, promoting self-regulation through positive parenting behaviors can ameliorate the negative influence of these factors.

Measuring and Promoting Self-Regulation

Self-regulation has become a primary focus for many researchers interested in early childhood education. This is likely due to an abundance of research documenting a direct relationship between self-regulation and academic achievement. This interest extends outside the realm of research and is now deeply embedded in class curriculum, policy, and even clinical diagnoses. Given that researchers, teachers, policy makers, and clinicians are beginning to understand the role of self-regulation within a continually broadening context of personal and academic success, it is critical that valid and reliable measures are used to assess self-regulation. In addition, classroom-based interventions in early education settings need to be implemented to promote self-regulation in young children. A sample of direct assessment, teacher-rated self-regulation measures, and classroom-based interventions is outlined below.

Direct Assessments

Head-Toes-Knees-Shoulders Task. The Head-Toes-Knees-Shoulders (HTKS) is a valid and reliable direct assessment of self-regulation that measures a confluence of attention, inhibitory control, and working memory skills in children ages 4 to 8, and has been found to be reliable in a number of diverse samples and countries. In this 30-item task, assessors outline a number of rule pairings (head-toes, knees-shoulders) and children are asked to touch the opposite of the item that is presented.

For example, when children are asked to touch their knees, a correct response is recorded if they touch their shoulders. As children advance through the task, rule pairings change and the task becomes increasingly difficult. The HTKS takes approximately 5 to 7 minutes per child to administer.

Dimensional Change Card Sort. The Dimensional Change Card Sort (DCCS) is a 24-item task that primarily focuses on attention or cognitive flexibility, one of the three components of self-regulation. In this task, assessors present children with a picture card. All cards in the deck vary on a number of dimensions, which can include (but are not limited to) size, shape, and color. Children are asked to sort picture cards on a specific dimension by sorting cards in stacks or boxes. This task is a reliable and valid measure of attention or cognitive flexibility for children ages 3 to 7 years old.

Teacher Reports

Child Behavior Rating Scale. The Child Behavior Rating Scale (CBRS) is a 32-item teacher-rated measure, of which 10 items measure self-regulation. Teachers are asked to rate a child's ability to demonstrate self-control within a classroom context by providing ratings on a Likert-type scale with responses ranging from 1 (*Never*) to 5 (*Always*). Many research studies have documented that this measure is reliable and valid in diverse samples of young children.

Classroom-Based Interventions

Although there are a number of classroom-based interventions aimed at advancing a generalized framework of knowledge for young children (i.e., math, reading), there have been few interventions developed to specifically target self-regulation skills in preschool-age children. One classroom intervention, developed by Shauna Tominey and McClelland (2011), capitalizes on an integration of music, games, and activities to advance self-regulation skills in young children. Recent studies provide evidence of the effectiveness of these intervention games, showing that children who

were randomly assigned to the classroom-based intervention significantly improved their self-regulation skills over the course of the academic school year and also showed significant gains on measures of emergent literacy and mathematics. This classroom-based intervention requires minimal training and utilizes materials that are easily available in a classroom setting.

Other interventions showing positive effects on self-regulation and academic outcomes are the Tools of the Mind classroom curricula, the Kids in Transition to School program (KITS), and Head Start REDI. Overall, the results of these studies are promising and highlight the importance of utilizing valid measures and effective self-regulation interventions to promote these skills in children at risk for school difficulty.

Conclusion

A large body of research now documents the importance of children's self-regulation for healthy development and long-term social and academic success. This is especially relevant information for early childhood educators who are on the front lines of helping children develop strong social and academic readiness skills. Unfortunately, young children facing a host of sociodemographic risk factors such as poverty and being a low-income ELL are more likely to experience difficulty with self-regulation. However, there is also evidence that strong self-regulation can serve as a buffer or protective factor for children growing up in the context of risk. Using reliable and valid measures is critical to identifying children who may need additional help with self-regulation in the early years. Finally, a growing body of evidence suggests that interventions designed to promote self-regulation can effectively improve these skills with significant effects also found for improved academic outcomes. Thus, early childhood teachers and policy makers can use this information to promote healthy development in children from a diverse set of backgrounds.

SENSORY DEVELOPMENT

Sensory development refers to the maturing and advancement of the visual, auditory, gustatory, olfactory, and tactile senses, which begins in utero. Sensory development includes sensory integration, the receiving of input from the senses then responding appropriately. With the exception of sight, most of our senses are fairly well developed at the time of birth, as development begins in utero. The input from the senses is crucial, as they allow newborns to learn about the environment. The intensity of responses and attention to each sensory modality is unique to each individual. During the first months of life, the senses work together dynamically to learn about the world. This entry focuses on the typical development and characteristics of the five senses and how they are linked to one another.

Each sensory system is composed of receptors, neural relays that send information to the neocortex, and the representations within the neocortex. The sensory systems are diverse and may seem unconnected; however, they are organized in a similar way in the brain. Sensory receptors convert, or transduce, sensory energy into neural activity for each sense. Each sense is specialized for a specific

type of energy with different types of sensory receptors. External stimuli are responded to by exteroceptive receptors while interoceptive receptors respond to internal stimuli. In order to sense something, the energy that comes into each sensory organ is changed into action potentials. Each sensory organ has a receptive field, a part of the environment it responds to, and a response to identify change and consistency. The sensitivity of a sensory modality is determined by the receptive density. For example, there are more receptors in our fingers than our arms.

Tactile Sense

Tactile or touch refers to bodily sensations perceived through the somatosensory system that activates the mechanoreceptors, or cells that are extremely receptive to sensations like touch or pain. Pain is perceived when somatosensory receptors create action potentials and then tissue damage sends out chemicals to the brain to activate pain fibers as described by Bryan Kolb and Ian Whishaw (2009). The tactile sense is the most developed at birth. Matthew Hertenstein found that touch is crucial to the infant's overall well-being, as infants who are not held or touched can develop severe physical and cognitive issues. Additionally, tactile sensations have the remarkable power to communicate many emotions to children, including positive, negative, and discrete emotions, and convey very specific information to a child, such as the identity of a person holding him or her (Hertenstein, 2002).

Touch can positively influence outcomes, especially in premature infants. For example, in a study published in 2009, Smriti Arora found that premature infants who experience touch therapy are able to improve overall health and well-being. Kangaroo care is a specific form of massage therapy, which involves skin-to-skin contact between caregiver and infant that can regulate breathing and the heart rate, the results of which have inspired many hospitals in the United States to adopt similar methods. Several studies have demonstrated how massage reduces

stress in premature infants during their hospitalization including one by Maria Hernandez-Reif, Miguel Diego, and Tiffany Field in 2007. Another study by Field, Hernandez-Reif, and Julia Freedman in 2004 showed that when mothers were taught to massage their infants before bedtime, this process led to improvements in their weight, mood, and sleep.

Auditory Sense

Newborns are born equipped to process sounds and learn speech and language through the auditory modality. Audition occurs when air pressure waves turn into mechanical energy, which then activates auditory receptors, producing action potentials that are used to create perceptual representations as described by Kolb and Whishaw in 2009. There are two forms of interpreting pressure waves. Sound localization is the identification of the source of waves and echo localization is identification of waves reflected from objects.

An infant's sense of hearing is fairly well developed at birth as auditory developmental processes begin in the third trimester. Barbara Kisilevsky and colleagues found that infants become accustomed to hearing sounds from the outside world in the womb, such as a mother's heartbeat, stomach digesting, cough or sneeze, and voice (Kisilevsky et al., 2009). Infants remember the voices of their primary caregivers after birth and show preferences for them. A classic study by Anthony DeCasper and Melanie Spence in 1986 showed that newborns not only recognize their mothers' voices but remember the book that was read to them by their mothers during the last month of pregnancy.

Robin Cooper and Richard N. Aslin (1990) have shown that infants respond better to high-pitched and somewhat drawn out, exaggerated voices or infant-directed speech, because along with immature hearing abilities, the ear contains leftover amniotic fluid, slightly impairing hearing. Infants are able to focus when being spoken to in calm, sweet, and engaging tones that are pleasing to their sensitive developing ear. Though coordination is still developing, infants can turn to where a

sound is coming from as their hearing advances, becoming more refined.

Olfactory Sense

Olfaction occurs when chemical molecules carried by the air or contained in food fit themselves into epithelium receptors of the nose and carried directly to the limbic system in the brain allowing us to distinguish as many as 10,000 different odors (Kolb & Whishaw, 2009). The development of smell begins in utero and matures by the end of the first trimester. Amniotic fluid that surrounds the fetus takes on the odors of foods consumed by the mother leading to similar smell and taste preferences in the child which provides the first understanding of the culture he or she will inherit at birth as researched by Julie Mennella (2009). Mennella (2008) also noted that after birth, newborns are sensitive to the smell of amniotic fluid and breast milk; which provides a reference for the infant of foods that are safe for consumption. In fact in 1975, Aidan Macfarlane found that infants as young as six days are able to tell the difference between their mother's and another mother's milk. Newborns use their sense of smell to find their mothers and communicate when hungry. They respond to the scent of their mother's breast milk by making movements with their mouths and seem anxious to be fed, as found in research by researchers such as Katsumi Mizuno and colleagues in a 2004 study and Heili Varendi and Richard Porter in a 2001 study.

Infants show a preference for sweet smells compared with sour, bitter, or unpleasant smells through their expressions, which is the easiest way to determine whether an infant likes a smell according to Jacob Steiner (1979). It is also worth noting that there exists a "prime time" for introducing smells to a newborn. A 2007 study by Olga Romantshik, Porter, and Varendi found that when infants were tested on the ability to recognize an odor presented within 12 hours after birth a few days later, only newborns that had been presented with the odor immediately after birth were able to recognize the scent. Smells create memories and associations that influence preferences later on.

Gustatory Sense

Gustatory senses engage in a complex interaction of taste, temperature (hot and cold), texture, and smell influencing the sense of taste. Taste, smell, and trigeminal nerve stimulation determine the flavor of what we eat. Chemical molecules are either carried in the air or stored in food, and saliva helps dissolve food, which reacts with taste receptors buried around taste buds on the tongue. Taste buds begin to develop before birth as noted in a summary by Richard Doty and Muhammad Shah in 2008 and mature as the baby tastes what the mother consumes through the amniotic fluid (Mennella, 2009). This leads to taste preferences similar to those of the mother, especially if she breastfeeds after birth. The five primary tastes are sweet, salty, bitter, sour, and umami. Newborns appear to sense all of these tastes with the exception of salt, which they are unable to sense for the first few months of life (Doty & Shah, 2008). Newborns prefer foods that are sweet, observed in their preference for breast milk, and continue to develop preferences for foods similar to those ingested by the mother during pregnancy.

Early experiences with flavors influence later food preferences as Mennella found in several studies she conducted. In 1997, Mennella and Gary Beauchamp found that mothers who drank carrot juice during pregnancy or while breastfeeding had infants who displayed fewer negative facial expressions while eating a carrot-flavored cereal. Furthermore another study published in 2006 by Mennella, Janice Kennedy, and Beauchamp found that infants who are fed a hydrolysate formula consume more broccoli and cauliflower than those fed a milk-based formula. This and other research supports the importance of exposing infants to a variety of flavors prenatally and later through breastfeeding because it is linked to flavor acceptance in childhood.

Visual Sense

A child's development is heavily affected by the way vision develops. However, vision is the least developed sense at birth and is vastly different

from the sense of vision in an adult. The ability to see occurs when the cornea bends light as it enters the eye then light moves to the lens and is bent further to create a visual image on receptors at the back of the eye so it is perceived, as explained by Kolb and Whishaw (2009). Although a child can be born with very healthy eyes and proper connections, the eyes need time and stimulation to become fully developed.

At birth, vision is limited to the distance from the infant's face to the eyes of a person who is holding him or her, or about 8 to 10 inches according to Martin Banks (1980). In Robert Fantz's 1963 study, he found that infants prefer looking at the human face and have the ability to determine the outline of a person's face. Around 1 month of age, the infant's accommodation is similar to that of adults (Tondel & Candy, 2008). Eye movements are not well coordinated in the beginning and need time for eye muscles to strengthen and mature in order to focus on things farther away. Young children also have more difficulty scanning and attending to objects, people, and other resources to gather information. In a 1968 study by Eliane Vurpillot, a group of children were shown pictures of houses and asked to determine similarities and differences between them. The reflection in the children's eyes was filmed as they attended to the pictures. By tracking the eye movements, he found that children under 6 years of age had unsatisfactory answers because they looked only at portions of the pictures and did not look long enough at the pictures.

Infants also have limited color vision in the beginning, which improves over time. Around 2 months, infants are able to distinguish some colors (Kelly, Borchert, & Teller, 1997). In 1963, Fantz published a study revealing that once babies have developed color vision, they enjoy bright colors, high-contrasting patterns, and movements the most.

Other Senses

The proprioceptive, vestibular, and visceral senses are less often mentioned but just as important. Proprioceptive sensations are caused by contraction and stretching of muscles and the bending, pulling, straightening, and compression of the

joints between the bones. Input to the brain is unconscious to us; therefore we are not aware of these sensations. Vestibular senses perceive gravity and movement. These are sensed through the labyrinth in the inner ear. As we move, tiny carbonate crystal receptors are attached to hairlike neurons that send information about gravity to the brain stem. Another vestibular sense is movement. As the head changes direction in any direction, information is sent to vestibular nuclei and reports changes in movement through the semicircular canals in the ears. Input is received in the brain stem, which is coordinated with other senses. These senses begin developing early in prenatal development and are well developed by birth. The visceral sense provides information about blood flow, blood chemicals, and activity to the autonomic nervous system that helps regulate blood pressure, heart rate, digestion, and other functions.

Issues With Sensory Development

On a final note, one should not view each sense in isolation. An issue with one sense can lead to complications with others, as well as affect the child's overall health and well-being. For example, a child's inability to hear may delay his language abilities and impair interactions and relationships with others. Thus, it is crucial for caregivers to understand how each sensory system develops to ensure optimal overall development. Many who work with young children find it challenging to figure out what a child is thinking. However, if one just stops and closely observes the child's behavioral responses to touch, sound, light, smell, and taste, this task will likely prove to be far less of a challenge.

SENSORY INTEGRATION

As first described by A. Jean Ayres (1989), sensory integration is defined as “the neurological process that organizes sensation from one's own body and from the environment and makes it possible to use the body effectively within the environment” (p. 5). It is this process that enables us to make sense of our world by receiving, registering, modulating, and interpreting information that comes to our brains from our senses. Ayres is known as a pioneer in the development of sensory

integration theory as an approach for occupational therapists to use in treatment. She approached sensory integration with a neurobiologic model and linked the neuropsychological processes to abilities and observed behaviors. As with all theories, sensory integration has a set of assumptions underlying it that propose to explain observed phenomena.

Sensory integration explains the way the sensory systems are organized for use. According to Ayres, “Sensory integration includes perception, modulation, and integration of sensory information as a foundation for participation in activities across social, physical, learning, and daily living tasks” (Schaaf et al., 2014, p. 149). Since these systems do not develop independently, understanding how they are organized and integrated is important, because together they form the underlying foundation for learning. Sensory integration is an unconscious process that occurs in the brain. It includes organization of the senses and helps us understand what we are experiencing and pay attention to what is important. Sensory integration also allows us to respond appropriately and purposefully and is the foundation for learning and social behavior.

Levels of Sensation

There are three levels of sensation that help us to understand ourselves and our surroundings. The first level is the exteroceptors, which are sensations that come into the body through the major sensory systems and include visual, auditory, gustatory, olfactory, and tactile senses. Next, the proprioceptors provide information about where our body is in space and how it is moving and include the vestibular and proprioceptive senses. Vestibular senses help with balance, gravity, and head movement while proprioceptive sensations help with position and movement. In 2014, Chia-Ting Su and L. Diane Parham further suggested that the association between the vestibular and proprioceptive systems is so strong that they could be interpreted as a single system. Finally, the visceral sense provides information about the inside of the body, according to Ayres.

Levels of Development

Ayres further hypothesized that there are four levels in the development of sensory integration. The first level is the stimulation of the senses and includes the senses such as auditory, vestibular, proprioceptive, tactile, and visual. The senses take in information about the environment and are developing as the infant learns how to use each to perform certain functions, such as feeding. The next three levels are the integration of the input of the senses into higher order functions going from more basic tasks, like eye movements and posture in stage two to coordination of the two sides of the body in stage three to eye-hand coordination in stage four. Sensory integration development is a fluid process. The fourth level pulls together all the learning in the previous levels involving the whole brain leading to end products such as the ability to concentrate and organize, engage in critical thinking, and have self-esteem and self-control.

These levels are forming as the child develops from infancy, where primary development of level one occurs, to age 6, where most work is done at the last level. This development is fluid. For instance, an infant is learning about his body in space and what each touch means while a toddler is integrating the sensations at both the primary and second levels with some focus on the third level of integration. By age 6, the primary level is done (understanding sensations), and much of the focus is on the final level (integrating sensory information in more purposeful activities and engaging the whole brain), though there is still some work on the second and third levels. Children work on the same things over and over though in different tasks relevant to their developmental age. A child transitions from sensing things visually (first level), to eye movements (second level), to attending to a sensation and motor planning (third level), to, finally, coordinating eyes and hand movements and grasping items (last level). According to H. M. Leong, Jennifer Stephenson, and Mark Carter (2014), the development of effective sensory integration leads to stronger critical thinking in academic areas

along with improved fine and gross motor coordination.

Sensory Integration Dysfunction

Ayres posited that some children have impairments in sensory integration that manifest as difficulties observed in purposeful behaviors. The term *dysfunction* is used to describe a problem or malfunction in integration that can potentially be reversed. It does not imply a complete lack or absence of function, according to Ayres. Utilizing factor analyses combined with standardized measures of sensory integrative dysfunction, Ayres was able to identify and confirm patterns in the deficits. A dysfunction in sensory integration may explain why some children have trouble learning new skills, regulating their attention, participating in school or play activities, and engaging in positive social experiences. For example, one child may sense a person's speech as overwhelming and aversive while another may not sense the speech at all at a typical auditory level. Some sensory integration dysfunctions include developmental dyspraxia, visual perception, visual discrimination, form and space perception, visual-motor functions, tactile defensiveness, vestibular and postural deficits, and deficits in auditory and language functions. Children with autism have special sensory integration needs and challenges.

Ayres, and many who have followed her, have worked to establish the validity of this theory through clinical and basic science research, for example, by Leonard F. Koziol, Deborah Ely Budding, and Dana Chidekel; Zoe Mailloux and Heather Miller-Kuhaneck; and Teresa A. May-Benson and colleagues. Over the decades, researchers and clinicians have explored different ideas and treatment strategies with regard to sensory integration. As the concept of sensory integration has evolved, terminology used to describe these differing perspectives has emerged, and a large portion of the studies published on sensory integration have had methodological flaws or minimal to no reports on fidelity, according to the American Occupational Therapy Association (AOTA) and Mailloux and Miller-Kuhaneck.

To clearly distinguish the program of therapy developed by Ayres, the Franklin B. Baker/A. Jean Ayres Baker Trust trademarked the term *Ayres Sensory Integration*. Susanne Smith Roley and colleagues suggest that the use of this term indicates observance of the core principles of Ayres's original theoretical framework, distinguishing it from other theories of sensory integration. Terminology specific to the Ayres trademark includes (a) sensory-based strategies, (b) sensory integration, (c) sensory processing, (d) sensory processing deficits, and (e) adaptive response.

Another individual who has made significant contributions to the understanding of sensory processing and related developmental issues is Winnie Dunn. In 1997, Dunn first proposed the Quadrant Model of Sensory Processing that uses two criteria: (1) response type and (2) sensory threshold to stimuli. Dunn's (1997, 2007) model of sensory processing was developed in the field of occupational and educational counseling. She proposed that four sensory processing patterns characterize the perceptual process. These patterns are thought to arise from individual differences in neurological thresholds for stimulation (high versus low) and self-regulation strategies (active versus passive). Crossing these dimensions provides four sensory processing styles.

Individuals with *low registration* have a high threshold with a passive response. A child with this processing style needs a lot of stimulation but does little to meet that need. *Sensory sensitivity* is a low threshold with a passive response. Children with this processing issue need very little stimulation, becoming overstimulated easily; however, they are not able to react accordingly to help themselves. The child will often have a tantrum or poor behavioral control after an overstimulating event but may show few behavior issues during the event. *Sensation seeking* individuals have a high threshold with an active response. A child who is a sensation seeker will try to fulfill a sensory need. He or she might eat grapefruit or spicy foods to meet a sensory need for flavor, chew on a pumice stone for texture, or lift heavy items before engaging in less stimulating activities.

Finally, *sensation avoiding* children have a low threshold with an active response; therefore, they need little stimulation for a sense to be overwhelmed. A child might leave the room when dinner smells become overwhelming.

It is important to recognize sensory processing may not be the same for each sense. Dunn and colleagues proposed that understanding interactions between neurological and behavioral concepts could help therapists interpret young children's behavior in order to help them function within their environments.

Identifying Sensory Integrative Dysfunction

To identify a sensory integrative dysfunction, occupational therapists must utilize a number of tools and methods such as standardized assessments (e.g., the Sensory Integration and Praxis Tests; Ayres, 1989) and through indirect measures such as parent- or teacher-completed questionnaires. It is important that therapists are able to discriminate differences across and among children; just because a child has a problem with sensory integration in one area/level does not mean he or she will have difficulty in another. Furthermore, according to Dunn, sensory integration dysfunction can present itself in very different ways across children according to age, which sensory systems are involved in a task, or even the child's capacity for that day (e.g., rested or tired).

Some examples of sensory integrative dysfunction include the following. Infants displaying sensory integration difficulties may not roll over, sit, or stand at expected times for these developmental milestones. If a child falls into the sensation avoiding pattern, based on Dunn's model, then he or she will tend to withdraw from situations quickly that are overstimulating, such as peripheral sounds and lights found in daily activities. Children with sensitivity may also be irritable, short-tempered, or even demanding, as they may not have good self-regulation, according to Dunn, and the brain may not be "processing or organizing the flow of sensory impulses in a manner that gives the

individual good, precise information about himself or his world” (Ayres, 2005, p. 47).

Sensory Integration Therapy

Most of the practitioners who use sensory integration therapy are occupational therapists and, as such, the goals of intervention are aimed at enhancing a child’s ability to participate in daily occupations that are meaningful and satisfying for that child in a natural context. The route to achieving that goal is individually defined, but can be broadly categorized as aiming either to remediate underlying impairments or to enable participation through accommodation and adaptation, essentially two different roads to one place.

Sensory integration therapy (SIT) was originally developed by Ayres, and this form of therapy is sometimes referred to as classical SIT or now, according to the trademark, as Ayres Sensory Integration therapy. This treatment approach aims to provide the child with various sensory experiences. These experiences are matched during therapy with a “just right” challenge, and activity that requires the child to give an adaptive response. SIT is an active therapy. The child must be motivated and engaged in the choice of activities; hence, play is the medium of choice. Activities usually involve large pieces of equipment such as balls, trampolines, and suspended equipment that provide intense proprioceptive, vestibular, and tactile experiences. The child is encouraged to explore equipment and the therapist sets up activities and the environment to challenge the child to use sensory input to organize an adaptive response. It typically involves one-to-one direct intervention in an environment that has a variety of specialized equipment.

SETTING INFLUENCES ON CHILD DEVELOPMENT

Setting influences refers to the impacts of the physical environment (including toxins and pollutants, noise, crowding, chaos, housing quality, school and child care quality, and neighborhood quality) on children's development and well-being. In this entry, the impact of each of these factors is discussed. Much of the current evidence comes from research in the United States and Western Europe. Where possible, research evidence in other contexts is discussed. Where the research is limited, recommendations for future research are outlined.

To better frame known and recommended future research and practice, a holistic, multidisciplinary, and multilevel approach based on Urie Bronfenbrenner's bioecological model is discussed. Recommendations for more extensive research in the Global South (countries with a low to medium Human Development Index score) and the provision of space and time to play in indoor and natural outdoor settings are outlined. This approach is intended as a way to better understand and reduce the aversive effects of multiple environmental risks on the development and well-being of children across the globe.

The Physical Environment and Child Development

There is mounting evidence, particularly in North America and Western Europe, documenting significant impacts of the physical environment on child development. There is also a growing body of research documenting such impacts on children growing up in varying contexts around the globe, with the strongest evidence coming from middle-income, newly industrialized countries. Key physical environment factors include exposure to toxins and pollutants (heavy metals, pesticides, air and water pollution), noise, crowding, chaos, housing quality, school and child care quality, and neighborhood quality. Unfortunately, particularly in low-income homes, schools, and neighborhoods,

the impacts of individual aspects of the physical environment are unclear, since multiple environmental risks tend to be correlated.

In addition, little is known about the interaction of multiple risks on development, although these impacts appear to be cumulative. To further study the impacts of the physical environment on child development and develop effective interventions to improve the physical environment experienced by children, it is essential to develop a conceptual framework that captures the complex interrelations between multiple physical environmental factors operating at multiple levels. Bronfenbrenner's bioecological model serves such a purpose.

Theoretical Approaches

Bronfenbrenner's bioecological model outlines four interacting dimensions: (1) process, (2) person, (3) context, and (4) time (PPCT). *Process* denotes exchanges of energy between an individual and his or her environment over time. Enduring, progressively more complex reciprocal interactions between persons and their immediate environments, or *proximal processes*, are the "engines of development." The impact of proximal processes on development varies as a function of characteristics of the developing *person* (e.g., self-esteem, gender) over *time* (e.g., daily book reading with a caregiver in the first 3 years). Finally, development occurs within four nested and interacting levels of context: (1) the microsystem (including physical settings directly experienced by the child, e.g., books available at school), (2) the mesosystem (connections between microsystems, e.g., access to books at home and at school), (3) the exosystem (settings that influence the child, although the child isn't directly exposed to them, e.g., the distance between a parent's workplace and home), and (4) the macrosystem (overarching interactions between micro-, meso-, and exosystems, e.g., government policies regulating noise levels). Many of the known physical environment factors impacting child development operate at the microsystem level, with some (e.g., noise, crowding, chaos) functioning by interrupting proximal processes, while others might better

support these processes (e.g., availability of books at home and at school). Much less is known about the impacts of physical environment factors operating at other levels. Further work needs to be done in these areas.

Key Setting Influences

Toxins and Pollutants

Exposure to lead and mercury from the prenatal period through adolescence impacts children's attention, learning, and behavior. Prenatal exposure to polychlorinated biphenyls (PCBs) impacts later cognitive and social-emotional functioning. Direct and indirect (through parents' clothing) exposure to pesticides used in agricultural production has similar effects. Unfortunately, there is limited regulation of many of these toxins and other soil, air (e.g., nitrogen dioxide from traffic fumes and environmental tobacco smoke), and water (e.g., arsenic and manganese) pollutants in newly industrialized countries and in the Global South. For instance, lead paint is still used in the production of toys and other household products in China. Even when these compounds have been regulated for many years, as is the case for lead in the United States, they remain in the ecosystem for a long time. For example, lead is found in the soil, paint, and plumbing of older houses and schools. Finally, water sanitation and waste management are particularly salient for children's development in the Global South and in low-income settings across the globe. Waterborne diseases significantly impact cognitive development and school performance, both directly and as a result of malnutrition derived from exposure to bacteria-contaminated water. In addition, illness and malnutrition lead to increased absences from school and problems paying attention in school. The need to walk long distances to obtain clean water may impact girls' school attendance in particular.

Noise

Early and chronic noise exposure significantly impacts children's reading acquisition in the Global

North, perhaps by impacting the development of long-term memory, attentional strategies, and speech perception. Some research documents similar impacts in the Global South. In addition, children exposed to noise both at home and at school have worse reading outcomes. In noisy homes and schools parents and teachers may talk and read less to children, and be generally less responsive, perhaps as a result of fatigue and the physiological stress associated with chronic exposure to unpredictable and uncontrollable noise. Repeated, unpredictable, and uncontrollable noise undermines the motivation needed for academic achievement, in both the short and long term.

Crowding

Despite differences in perceived tolerance for crowding across different cultural contexts, there is significant evidence from multiple contexts documenting the impacts of crowded homes and schools on cognitive and behavioral development, school achievement, and reading comprehension across the life span. In infancy and early childhood, crowding disrupts children's exploration, play, and interactions with people and objects. In addition, residential crowding may disrupt parent-child interactions: Parents in crowded homes talk less and in less complicated ways with their children. Residential crowding may also reduce children's ability to complete homework, reduce parental monitoring, reduce parental responsiveness, increase family conflict, and increase parental and child withdrawal from interaction. Children in crowded homes and schools also show higher levels of aggressive behaviors at home and school, and their parents are more likely to use physical discipline. Increased levels of physiological stress in crowded homes and schools may partially explain these outcomes, particularly for low-income children.

Chaos

Chaos (noise, crowding, and other factors interrupting structures and routines) significantly impacts cognitive and social-emotional

development, perhaps due to a disruption of the proximal processes (regular, sustained exchanges of energy between children and people and objects in their immediate settings) that drive development. For example, parents in chaotic homes may provide fewer opportunities for learning and be less responsive.

Residential mobility resulting from a lack of legal tenure may lead to an ongoing disruption of daily routines for children, thus significantly impacting their academic achievement and social-emotional well-being. Children living in informal housing, particularly in the Global South, are much less likely to attend school.

Housing Quality

There is limited research on the impacts of specific aspects of housing quality on children's development, particularly in the Global South. However, substandard housing significantly impacts children's cognitive and social-emotional development, perhaps because children are exposed to higher levels of lead and other toxins, air pollutants, and pests. In addition, their parents experience higher levels of stress, thus potentially leading to reduced warmth and responsiveness. In environments that are unsafe, caregivers constrain play. Space and furnishings, such as room arrangement and displays for children, may be moderators for the negative impacts of crowding. Access to books, learning materials, and other resources such as electricity, a radio, a television, and a telephone at home may also impact cognitive and social-emotional development, with access to play materials being particularly important.

School and Child Care Quality

School quality clearly impacts children's school achievement, although specific individual effects are less well understood. School and classroom size have salient impacts on children's academic achievement across multiple contexts, and there is growing evidence for impacts of the quality of building infrastructure (including lighting, access to electricity and water, structural quality, indoor climate,

and sanitation) and access to resources (textbooks and books, desks and chairs, blackboards, technology, and school libraries). Children attending poorly maintained schools are exposed to mold and other allergens that lead to asthma, allergies, and upper respiratory infections, and thus school absenteeism. In addition, a poorly maintained school building may signal to students that not only are building standards low but so are academic standards. Thus, student achievement suffers.

In North America and Europe, there is some evidence that open plan classrooms are noisier and thus distracting for children. However, classroom organization can counter some of these impacts with separate activity areas and secluded, cozy areas for children in early childhood environments. School settings also impact teachers' well-being and responsiveness, as well as satisfaction and thus retention.

Neighborhood Quality

As with home and school quality, it is difficult to parse out the impacts of individual components of the physical environment of neighborhoods. However, the vast majority of children growing up in the Global South live in neighborhoods with high levels of air and water pollutants, poor sanitation, high levels of street traffic (thus leading to noise and safety concerns), poor street lighting, and very limited access to schools, hospitals, grocery stores, and open green and other play spaces.

The Physical Environment and Play

When asked, children growing up in diverse urban contexts around the world are particularly aware of a lack of access to green play spaces. There is a growing literature documenting the impacts of play, particularly play in natural settings, on children's academic achievement, social-emotional well-being, and physical health. Children engage in more complex play in natural settings at home and at school, and there is some evidence that proximity to such settings enhances well-being and reduces the impacts of crowding, noise, chaos, and stressful life events on both children and the adults who care for them.

Future Directions

The physical environment experienced by children impacts their development and well-being from the prenatal period through adolescence. Thus, the development of effective interventions to improve the physical environments experienced by children is essential. However, given the multiple impacts of multiple components of the physical environment, it is important to identify key influencing factors. During early childhood, factors contributing to chaos (including noise, crowding, and residential mobility) in home, school, and neighborhood environments may have particularly salient impacts on children's development and well-being as they interfere with effective proximal processes, operate across multiple levels, and impact both children and the adults who care for them. Access to natural settings, especially open green spaces for play, may counter the impacts of chaos. Community adventure play experiences, temporary play spaces within children's own communities that engage them in interactive play with recycled and natural materials, are a particularly low-cost and sustainable approach to increasing opportunities for children's play in low-resource settings.

SEXUALITY DEVELOPMENT

Sexuality development in young children refers to multiple developmental processes that are connected to knowing about one's body, physiological responses, gender identity, and respectful relationships. Kent Chrisman and Donna Couchenour have elucidated ways that children's healthy sexuality development is related to physical, cognitive, social, and emotional development. Each of the developmental processes is involved in young children's healthy sexuality development as sexuality is viewed as an aspect of being human, and not just as sexual activity.

Physical Development and Behaviors. It is natural for young children to express interest in their bodies and to explore their body parts, including genitalia. Over time, they gain control of their bodily functions, including large and small muscles and those involved with elimination. Children make adjustments in their physical behaviors as their bodies change as they get older.

Cognitive Development and Behavior. Children express curiosity about their own bodies and those of others. They learn about bodies the same way that they learn about everything else, through experience and interactions with their world. As young children are able to identify themselves as boys or girls, they also become aware of gender identification of other children and adults. As they gain experience in their families and communities, children become curious about human biological systems, including reproduction.

Social Development and Behavior. Healthy sexuality development is dependent on social interactions that are required for all aspects of children's optimal growth. Young children who are responsively nurtured are given the necessary basis for their lifelong sexuality development. Such nurturance also paves the way for positive relationships with peers and other adults and assists children with their ability to understand and respond to behavioral limits set by caring adults. An understanding of moral judgments considering differences between right and wrong is also associated with early trusting relationships. Young children observe and begin to practice traditional gender roles from their own cultures and experiences.

Emotional Development and Behavior. The self-esteem of young children is established in multiple ways with nurturing adults setting the stage for positive feelings about the self. Children with positive self-esteem are able to express affection and caring for others, to demonstrate respect, and to empathize with others' feelings and viewpoints. Over time and with supportive interactions, young children learn to manage emotions such as joy, sadness, and anger in ways that are appropriate and expected.

Sexuality Development Differs for Children and Adults

A discussion of young children's healthy sexuality development differs from an understanding of adult sexuality in several ways. It is critical for those who parent or teach young children to understand that children's curiosity and interest in sexual-themed topics and behaviors is in itself not a reason for apprehension, but a reflection of both their humanness and their experiences. Fred Rothbaum, Avery Grauer, and David Rubin explain three key distinctions:

1. Children are curious and playful whereas adults have sexual knowledge and are responsible for their related decisions and behavior. It is not unusual for young children to touch their own

genitals in a public place or to ask a question about pregnancy loudly, such as, “Mama, why is that lady’s belly so fat?” Healthy adults would not be likely to have similar behaviors.

2. When it comes to sexual topics or behaviors, children are as spontaneous and open as they are about any other topic whereas adults engaging in healthy sexual behavior are deliberate and private. Toddlers who are curious about their bodies may not understand that shedding their clothes in a living room with visitors present is not preferred behavior. Privacy is key for healthy adult sexual responses.

3. Young children typically find the topic of sexuality attractive and at the same time repelling. Although it is common for them to imitate the sexuality of adult models that they see in their families or in the media, they do not possess the eroticism of adults due to both levels of understanding and biological differences. Preschool or kindergarten teachers may observe children holding hands, kissing their “boyfriends” or “girlfriends,” and making declarations about who they will marry, but these behaviors have the innocence of childhood integrated into models from adults in their world. Adult meanings for significant others and marriage often have an element of eroticism based in part on mature biological systems.

Developmental Expectations Through the Early Childhood Years

Behavior and understanding related to healthy sexual development in young children varies based on age and experience. This section explains typical expectations for infants and toddlers (birth to 3 years), preschoolers (3 to 5 years), and kindergarten and primary grade children (5 to 8 years).

As infants explore all aspects of their environment, many caregivers delight as babies “find” their fingers and toes. When babies explore their genitals during a diaper change, adults are less enchanted. Adults who understand that this is typical behavior that is pleasurable to very young children may see that this is one of the important

differences between adult and child sexuality. Infants and toddlers begin to have either positive or negative approaches to their own bodies. Adults who engage in supportive interactions during diapering and pottyng explain what is happening and help to keep children comfortable. Although cultural, familial, and individual variations exist in terms of gender identity, children at this early age develop preferences based on their biological and environmental experiences. Adults who respect infant and toddler developing preferences rather than correcting them to fit into narrow definitions of male and female will find that this respect leads to a child’s positive self-esteem, an essential characteristic for all healthy development.

Preschoolers continue to increase their awareness and curiosity about their own bodies, differences in bodies, and gender identification. Just as caring adults support children’s curiosity about other aspects of their world, adults who support curiosity about bodies in authentic and sensitive ways contribute to children’s healthy sexuality development. Inquisitiveness at this age extends to children wondering where they came from and some aspects of reproduction. Adults who respond with concise and truthful answers confirm children’s interest in human biology. Sometimes troubling to caregivers, preschoolers often masturbate and engage in sex play with peers. Teaching children that touching genitals is private behavior will help them to begin to increase self-control. Reducing children’s boredom and stress is also key to this concern.

Close supervision of preschoolers is necessary for many safety reasons, including inappropriate touching of others. Children at this age have a rapidly growing vocabulary and high interest in new words, including those deemed as cursing. In order to reduce this tendency, adults must model expected language and apply positive guidance such as providing alternative words. Along with having an increasing vocabulary, preschoolers have an affinity for “bathroom humor.” Nothing is funnier than calling something “poopy.” An understanding that children find this to be funny

helps adults to not overreact, but to apply positive guidance techniques including ignoring the phrasing at times.

In relation to gender identity, preschoolers create firm beliefs about whether they are male or female. Generally, this belief is consistent with their biology. However, adult responses may be confusing to young children who are biologically female and identify as male or who are biologically male and identify as female children; the children may not understand why the adult responds to them as male when they identify as female, or vice versa. Research is ongoing in the areas of gender identity disorder and transgender identification. Stephanie Brill and Rachel Pepper point to neurodevelopmental rather than environmental associations for children who are biologically one sex and identify with the other. At present, the best advice for parents and teachers is to support children's interests as they are as interventions will not be successful and are most likely to be harmful. As with all individual differences in young children, responsive caregiving and acceptance of individual interests leads to optimal development.

Kindergarten and primary grades children continue some of the same behaviors and attitudes of preschoolers. Sex play and masturbation are expected behaviors, but caring adults must intervene to teach children that it is not acceptable to touch other children's genitals and that touching one's own genitals is private behavior. Much of 5-through 8-year-olds, social behavior is focused on their gender identity: engaging in somewhat rigid gender roles, stereotypical play and activities, and strong same-sex friendships. Just as with younger children who may identify as transgender, kindergarten and primary age children are likely to favor gender identity in their friendships and activities. New social behaviors during this developmental period that are likely to be observed are teasing, name-calling, and bullying. Families and teachers of young children must be keenly aware and plan to explicitly teach children about the harmful effects of such behavior. Developmentally, children at this age are able to learn about these effects but may not understand or empathize on their own accord.

Roles of Families and Schools

Parents are children's primary educators about sexuality and gender. Much of children's early learning about their bodies, femininity and masculinity, and limits on behavior happen in family settings. As children's first teachers and primary attachments, adults who are parenting young children have responsibility for their early understanding of sexuality. However, many parents either do not consider this a topic for parenting young children or are uncomfortable thinking about a life span view of human sexuality. For this reason, schools and communities have a role in supporting families as well as providing care and education for young children.

Chrisman and Couchenour found in focus group research that many teachers of young children often experience classroom dilemmas related to children's interest in bodies and reproduction but have not had formal preparation for responding to such situations. While many teachers report applying variations of positive guidance, others indicate that they respond in negative ways, such as telling children "That's not nice," calling parents without solutions to share, or ignoring behavior that makes them uncomfortable. Many teachers, especially those with less experience, report that they are uncertain about what is developmentally expected at various ages and which behaviors may cause concern about sexual abuse. Thus, a need has been established to help teachers respond in knowledgeable ways that are supportive of children's typical level of curiosity, set reasonable limits, and partner with families. Mary Sciaraffa and Theresa Randolph point out that in addition to gaining knowledge, teachers must become comfortable in order to best support healthy sexuality development in young children.

Differences in families must be understood by early childhood teachers. Some variations include the following:

Within Family Communications About Sexuality. Some families may openly and authentically discuss related topics and use anatomical terms for

body parts while others may have nicknames for male and female genitalia and much less open discussion. Children will come to school demonstrating these variations.

Family Space and/or Value for Privacy. Some families openly share sleeping and bathroom space leaving less opportunity for privacy. Others may insist on privacy at various times. Children will come to school with different views about public and private behaviors.

Media Offerings and Limitations. Some families may strictly regulate what young children watch on screen and others may allow children to be exposed to sexuality that is beyond their level of comprehension. For some children, this causes stress and acting out.

Exposure to Prejudice. Some families practice an anti-bias approach to gender and sexual orientation. Other families may openly indicate prejudices. Although young children have difficulty comprehending deep meaning of such prejudice, they may demonstrate overt prejudice in classrooms.

Attention to anti-bias efforts is related to early childhood professionals' support of young children's healthy sexuality development. As teachers model tolerance, fairness, and respect for all individual differences, they create an environment of warmth and empathy for all.

Children's Behaviors That Are Indicators for Concern

Although the premise of this entry is to provide information about young children's healthy sexuality development, an examination of child behaviors that should cause concern regarding a need for intervention is included to demonstrate that some behaviors are not typical of young children. Francis Wardle has compiled this list of children's behaviors that should receive immediate attention from adults and are cause for intervention and in some cases referral to determine whether the child has been sexually abused:

- A child who complies with intrusive or painful activity by another child
- A child who engages in self-inflicted painful sexual activity
- A child who engages in oral/genital contact with another child
- A child who engages in simulated intercourse while undressed
- A child who penetrates a girl's vagina with a finger or other object
- A child who forcefully enters any orifice in another child with a finger or other object

Common to these unhealthy behaviors is that they are aggressive and require compliance of another child. When parents or teachers observe these behaviors, it is necessary that they tell children to stop, put their clothes on, and follow through with help for both children.

SHYNESS IN YOUNG CHILDREN

In the past 30 years, a burgeoning literature has accumulated on the topic of children's shyness. This entry describes the origins, correlates, and consequences of shyness in childhood—a phenomenon which, under particular circumstances, can bring with it the behavioral expression of solitude and wariness in social company, rejection and victimization by peers, and negative feelings of self-regard.

Defining Shyness and Related Constructs

In their efforts to identify the etiology of children's personalities and social behaviors, developmental scientists have attempted to determine the relevant dispositional dimensions of temperament that may underlie children's actions that are displayed consistently across situations and continuously over time. One such dispositional construct is *shyness*. Shyness has been conceptualized as feelings of emotional wariness in the face of social novelty and/or feelings of self-consciousness in situations of perceived social evaluation.

In many respects, the construct of *social reticence* represents a behavioral manifestation of shyness. This behavioral manifestation of shyness is marked by observations of the child hanging back in the peer group, watching peers from afar, rarely making attempts to initiate interactions with peers, and backing away from initiations made by others. When asked to speak up in groups of unfamiliar peers, shy or reticent children choose not to do so at all, and if they do speak, it is uncomfortably and

for a very short period of time. Further, when asked to collaborate with peers to solve problems, they spend their time watching others rather than providing the requested help. Social reticence putatively reflects internalized feelings of shyness that involve conflicted motivations of approach and avoidance. In this regard, shy, socially reticent children desire social interaction, but their social *approach* motivations are inhibited by fear-induced social *avoidance*.

The assumption that felt shyness is reflected, behaviorally, by socially reticent and inhibited behavior is supported by research demonstrating strong relations between adult appraisals (usually by parents and teachers) of shyness and observations of preschoolers' social reticence. During early childhood, feelings of shyness are elicited when confronted by unfamiliar children and adults. To some, the behaviors that accompany feelings of shyness serve an adaptive purpose in that they remove children from situations that they perceive as discomforting and dangerous. But variability of this early childhood response is great; some children clearly demonstrate shyness and social reticence excessively.

By the time that children enter elementary school, they have the cognitive skill to compare themselves with others and to understand that others can, and do, pass judgment on them. It is this understanding of social comparison and evaluation that can elicit shy or withdrawn behavior among older children, adolescents, and adults. That is, children may remove themselves from situations that they believe will be discomforting because others will pass judgment on their skills, personae, and so on. Again, variability is great; some children display shyness that is clearly out of the ordinary.

A related construct that has received a great deal of attention is *behavioral inhibition*. *Behavioral inhibition* has been defined variously as (a) an inborn bias to respond to unfamiliar events by showing anxiety, (b) a specific vulnerability to the uncertainty all children feel when encountering unfamiliar events that cannot be assimilated easily, and (c) one end of a continuum of possible initial

behavioral reactions to unfamiliar objects or challenging social situations. These definitions highlight some common elements: Behavioral inhibition reflects a pattern of responding or behaving to unfamiliar people, objects, and situations with signs of caution, anxiety, distress, avoidance, or disorganization. Indeed, the constructs of shyness, social reticence, and behavioral inhibition are highly correlated during the early childhood period.

It is important to note that the common denominator for shyness, social withdrawal, and behavioral inhibition is that the representative behavior is one that moves children *away* from their social worlds—*solitude*.

Developmental Origins of Shyness and Social Withdrawal

Biological Foundations

There is clear evidence that young children who are temperamentally shy and behaviorally inhibited differ physiologically from their more social and outgoing peers. According to Louis Schmidt and Arnold Buss, shy children have a biological profile that includes genetic predispositions to anxiety disorders and internalizing problems, neurophysiological functioning indicative of poor emotion regulation and a tendency to withdraw from novel stimuli, and an autonomic nervous system that is more reactive to stressors and less effective in regulating that reactivity. Though they may be important causes of shyness, these biological vulnerabilities are largely undetectable by shy children's interaction partners, operating quite literally below the surface. It is quite likely that shy, socially reticent children themselves do not fully understand their own bodies' responses to novel stimuli. What is clear is that these biological substrates provide the earliest known causes of shy and inhibited behavior.

Genetic Influences

Despite the inherent challenges of disentangling the roles of genes and the environment in shaping development, there is increasing support that allelic variations in the promoter region of a gene

for the serotonin transporter 5-HTT are related to higher levels of shyness, inhibition, anxiety, and negative emotionality. Carriers of the short allele of the 5-HTT gene produce lower levels of 5-HTT, which in turn results in less serotonin uptake in the synaptic cleft. Reduced serotonin uptake affects several important neural circuits in the brain, especially those involved in processing emotions. Neuroimaging studies have demonstrated that individuals with at least one short allele of this gene show greater amygdala activation in response to fearful stimuli (i.e., faces) than individuals who have two long alleles.

This increased reactivity to negatively valenced stimuli likely has consequences for children's psychological health. For example, children who inherit at least one short allele from their parents are more likely to be diagnosed with a pediatric depressive disorder. Despite this gloomy description, genes are not destiny. Nathan Fox and his colleagues have found that having the short allele for the 5-HTT gene was only related to inhibition and shyness when children experienced low levels of maternal support. The presence of the short allele may perhaps be best thought of in the context of a diathesis-stress model. While the short allele may predispose children to become inhibited, shy, and anxious, these predispositions need not develop into full-blown levels of psychopathology if children do not experience a lack of parental support, maladaptive parenting experiences, and/or such negative experiences as peer rejection and victimization.

Neural Correlates

Shyness has been increasingly linked with a particular pattern of activation in the frontal cortices. More specifically, children and adults who appear to have difficulty regulating their negative emotions and exhibit a tendency to withdraw from novel stimuli show evidence of greater right relative to left frontal activation. This finding linking right frontal asymmetry to inhibition and social reticence has been detected across a number of studies involving numerous labs and research groups.

The association between inhibition and greater right frontal asymmetry has been demonstrated in infants as young as 9 months. Moreover, infants who are inhibited and show increases in relative right frontal activation between 9 months and 48 months go on to become more socially reticent with peers as preschoolers. The importance of greater relative right activation, even at rest (i.e., not performing any tasks), is that the left prefrontal cortex has been conceptualized as a “brake” governing fear-related neural circuitry, whereas the right prefrontal cortex is thought to be associated with the “release” of the fear circuits. In sum, findings regarding the neurophysiology of shy children continue to paint a picture in which biological substrates that are more common among shy and inhibited children are related to increased difficulty in regulating such negative emotions as fear and anxiety.

Autonomic Nervous System Functioning

Mediated by the hypothalamic-pituitary-adrenal axis, the stress response is designed to help humans marshal needed resources in preparation for defending themselves from harm or fleeing from danger. As with other biological substrates, shy children exhibit differences in this important component of the autonomic nervous system relative to typical peers. For example, 4-year-olds who are wary in the company of peers have higher levels of basal cortisol in the morning than non-wary peers and tend to be rated as shyer by their mothers. Other biological markers of heightened sympathetic nervous system activity that may predispose young children to behave in a shy or wary fashion include a high resting heart rate, higher levels of norepinephrine, and lower respiratory sinus arrhythmia. For example, respiratory sinus arrhythmia (an indirect measure of vagus nerve functioning) is related to better functioning of the parasympathetic nervous system, which is responsible for down-regulating the stress response. Researchers have consistently shown that shy, socially reticent children are more reactive to stressors, and less capable of regulating such reactions.

Parenting and Shyness

While there is clear evidence linking temperamental shyness to physiological substrates, biology is not destiny, and children are quite malleable in their development, regardless of their genetic and physiological predispositions. Being a parent to a highly reactive and inhibited infant can be demanding, especially given that parents of highly reactive infants may share some of the biological vulnerabilities leading to their offspring's early temperament. Inhibited, shy children are often emotionally reactive (easily upset) as infants, and caregivers of these infants are less likely to behave in consistent, supportive ways that would lead to the formation of a secure attachment between child and caregiver.

Attachment theorists such as John Bowlby maintain that the primary relationship develops during the first year of life, usually between the mother and the infant. Maternal sensitivity and responsiveness influence whether the relationship will be secure or insecure. Researchers have shown that securely attached infants are likely to be well adjusted, socially competent, and successful at forming peer relationships in early and middle childhood whereas insecurely attached children may be less successful at social developmental tasks.

Some researchers have proposed that those infants who are temperamentally reactive and who receive insensitive, unresponsive parenting come to develop an insecure attachment relationship with their primary caregivers. In novel settings, these insecure babies maintain close proximity to the attachment figure (usually the mother). When the mother leaves the room briefly, these infants become quite unsettled. Upon reunion with the mother, these infants show angry, resistant behaviors interspersed with proximity- or contact-seeking behaviors. It is argued that this constellation of infant emotional hyperarousability and an insecure parent-child attachment relationship may lead to frequent displays of inhibited/wary behaviors in early childhood. Indeed, Cathryn Booth-Laforce and Monica Oxford have shown that inhibited infants and toddlers who form insecure attachment relationships with their primary caregivers are observed to display socially wary and reticent

behavior among peers during the preschool period and beyond.

Moving beyond the formation of an early attachment relationship, researchers have shown that parental influence and control maintain and exacerbate child shyness, inhibition, and social withdrawal. For example, Kenneth Rubin and colleagues have conducted several studies that better define the pattern of maladaptive parenting behaviors that tend to increase inhibited, shy young children's tendencies to withdraw. They have referred to this parenting style as *oversolicitousness*. Akin to the popularized term *helicopter parenting*, oversolicitousness combines overprotective control with strong displays of affection absent the child's display of distress. Essentially, oversolicitous parents prevent their children from engaging in autonomous activities that may otherwise allow for the development of effective self-regulation and coping skills. The lesson learned by shy and withdrawn children who experience this sort of parenting is that they are incapable of meeting the challenges of their environments without a parent there to assist them. These findings are one reason that early interventions aimed at disrupting the link between shyness and later internalizing problems often involve psychoeducation that targets the parent.

Correlates and Consequences of Shyness

It is now well founded that under certain circumstances, shyness, behavioral inhibition, and social reticence in early childhood place children at risk for several negative social and emotional outcomes. First, shy, behaviorally inhibited toddlers have been shown to demonstrate more socially reticent and solitary activity in the peer group than their unshy, uninhibited age-mates. Theoretically and empirically, it has been proposed and found that it is through peer exchanges that children come to (a) better understand and appreciate the thoughts and feelings of others, (b) develop knowledge pertaining to the consequences of their own social behaviors when directed at others, (c) develop a sense of self in relation to

others, and (d) develop an understanding of relationships. In turn, the development of these social and self-cognitions have been posited to predict the display of socially competent behavior in the peer group and rich, positive relationships with friends. As such, it should not be surprising that young children who refrain from peer interaction are less social-cognitively astute and less socially competent than their more sociable peers. Furthermore, these social-cognitive and social-competence deficits are associated with, and predictive of, peer rejection and exclusion. For example, when presented with vignettes about hypothetical socially competent and shy peers, preschoolers report that they would rather play and be friends with a socially competent child than with a shy child. Importantly, many of these findings are evidenced across cultures.

One of the "costs" of the combination of socially reticent behavior and peer rejection is the development of negative thoughts and feelings about the self. In particular, shy children who have experienced peer rejection and/or exclusion come to believe that they are lacking in social competence and that their peers dislike them; in turn, these thoughts and feelings about the self predict increases in social withdrawal.

The difficulties associated with early childhood shyness tend to persist throughout childhood and adolescence. Shyness tends to be moderately stable across childhood, and early behavioral inhibition predicts later social withdrawal. For instance, children observed to be behaviorally inhibited at 4 months of age are more likely to be socially reticent with a peer at 24 months of age than noninhibited children. Similarly, children who are behaviorally inhibited throughout early childhood and display an attention bias to threat (i.e., they are highly vigilant in social situations) are more likely to be socially withdrawn in adolescence than noninhibited children.

As noted earlier, early childhood shyness and social withdrawal hinders the development of social competence; thus, it is unsurprising that stable shyness between infancy and early adolescence is associated with lower social competence in early

adolescence. Finally, early shyness places children at risk of later anxiety disorders, particularly social anxiety. For example, it has recently been demonstrated that children who were very shy from ages 2 to 5 years old had higher levels of internalizing problems at age 5 than those with low or decreasing shyness. Similarly, researchers have revealed that young children observed to be highly behaviorally inhibited at some point between the ages of 1 and 6 years were significantly more likely than their noninhibited peers to have a diagnosis of social anxiety 5 years later, and children who were stably behaviorally inhibited between age 1 and age 7 were more likely than noninhibited children to be diagnosed with social anxiety disorder at age 15. In summary, shyness in early childhood is associated with less peer interaction, lower social competence, greater peer rejection and exclusion, and more internalizing problems and anxiety both concurrently and in later childhood and adolescence.

Importantly, however, parental behavior moderates the relations between early shyness and subsequent social and emotional problems, such that early shyness and inhibition only predict maladaptive outcomes when combined with negative parenting. For example, although children who display behavioral inhibition in infancy are at higher risk of anxiety disorders in adolescence, this relation has been found to hold true only for children with insecure attachments in infancy. Similarly, behavioral inhibition in infancy has been found to predict social anxiety disorder in adolescence only for those children with overly controlling mothers. Thus, although early shyness may predict later negative outcomes, behavioral inhibition and shyness only predict maladjustment if parenting experiences are also problematic.

Applied Issues

Because shyness places young children at risk of social and social-cognitive difficulties and later internalizing problems, researchers have developed several intervention programs to decrease anxiety and behavioral inhibition in young children. One intervention effort that has been developed to meet

the needs of extremely shy and inhibited young children is the Cool Little Kids (CLK) program developed by Ronald Rapee. In the CLK, clinicians teach parents of preschool-age children about the nature of anxiety and appropriate parenting techniques, gradually exposing children to stressors and addressing the parents' own anxiety. In the first evaluation of CLK, it was found that behaviorally inhibited children whose parents participated had fewer anxiety disorders 1 year later than children in a waitlist control group; also, the more sessions that the mothers attended, the fewer anxiety diagnoses the children received. At a 3-year follow-up, children in the intervention group were significantly less likely to be diagnosed with anxiety disorders than control group children. In addition, a more intensive 8-week version of CLK in which the children and at least one parent had anxiety disorders resulted in significantly reduced frequency and severity of anxiety disorders in the children, less interference of children's anxiety symptoms in daily life, and a decrease in children's observed inhibited behavior. These results demonstrate that a parenting intervention for shy children in early childhood can reduce the incidence of anxiety symptoms and disorders throughout childhood and adolescence.

More recently, the Turtle Program was developed for highly inhibited and shy preschoolers. This intervention combines Parent-Child Interaction Therapy focused on teaching parents to avoid intrusive or overly controlling behavior while praising children's social approach behavior, as well as a Social Skills Facilitated Play program. The latter part of the Turtle Program involves teaching children key interaction skills like initiating conversations, establishing eye contact, and regulating their emotions when in the company of other children and adults. Andrea Chronis-Tuscano and her colleagues recently reported that children in the intervention group had significantly fewer total anxiety symptoms and greater decreases in behavioral inhibition and internalizing problems than children in a waitlist control condition. In summary, recently developed interventions with young children have demonstrated

efficacy in reducing children's shyness and anxiety, with lasting effects.

SIBLING RELATIONSHIPS

Children's earliest interactions are those that occur in their families; given that most children in Western societies have at least one sibling, relations with brothers and sisters constitute an important part of the family system.

Sibling interactions have a number of unique features that differentiate them from children's other early relationships such as with parents and peers. First, inherent developmental and power differences between older and younger siblings in the same family lead children to take on different roles in sibling interactions. For instance, older siblings more frequently act as caretakers and teachers for their younger siblings than vice versa.

At the same time, because they are often relatively close in age, siblings engage in reciprocal and returned exchanges that are typical of peers, such as play. In this sense, sibling relationships are defined by both complementary (i.e., hierarchical) and reciprocal (i.e., equal, returned) features. Second, siblings spend a great deal of time interacting with one another. In fact, during early childhood, many children spend more time with their siblings than with anyone else, including their parents. As a result, they develop a long history of shared exchanges, thus establishing a common history together and potentially constructing an intimate bond. Siblings can, and often do, use this knowledge of one another's preferences, habits, and characteristics in both positive (e.g., to comfort) and negative (e.g., to tease) ways. Third, perhaps partly because of the amount of time they spend together, sibling relationships tend to be affectively intense, often characterized by strong positive, negative, and sometimes ambivalent emotions. Last, there are wide individual differences in the qualities of sibling interactions; these relationships vary dramatically in terms of both warmth and hostility, and some pairs can exhibit a blend of both characteristics.

These distinct features of sibling relationships are evident in the features of positive and negative interactions that are typically observed between young siblings. On the more positive side, friendly sibling relations in early childhood are associated with positive and adaptive functioning as children get older. Play is one important context in which siblings often engage in sustained and sophisticated forms of positive interaction, including pretense. Social pretense is associated with children's friendly interactions, their understanding of their social worlds, and their performance on formal measures of social cognitive ability such as their understandings of others' psychological perspectives. During pretense, siblings learn to negotiate in play to create joint understandings of play scenarios, transform objects, scaffold and extend one another's ideas, and use language that reflects the story characters' feelings and thoughts. Older siblings can be adept at scaffolding play interactions

for younger siblings and to engage them in collaborative ways. In addition, siblings frequently engage in warm and prosocial behavior, with older siblings more likely to initiate friendly, helpful interactions, and engage in caretaking and comforting. In turn, younger siblings are more likely to imitate and respond positively to their older sibling. Nevertheless, as younger siblings get older they become more active partners and are seen to take the lead more often during play and friendly interactions.

Siblings also spontaneously teach one another new skills and concepts about their physical and social worlds and use a range of sophisticated strategies such as verbal instruction, demonstration, and scaffolding to convey knowledge and involve the learner. Older siblings engage in more teaching about a range of topics such as math and literacy than younger siblings during ongoing interactions at home, but younger siblings also teach their older siblings at times.

On the negative side, many interactions between siblings are defined by high levels of conflict and rivalry. Observational research indicates that preschool-age children engage in conflict between three and 10 times per hour, most frequently about property-related issues (e.g., competition for shared resources in the home). Although these disputes provide opportunities for children to learn about moral issues such as property rights and ownership, conflicts between siblings are typically poorly resolved, and can also become emotionally intense or aggressive. Older siblings are especially likely to use power-assertive strategies (e.g., aggression) to get what they want at the expense of younger siblings; this is especially true when younger siblings do not defend themselves. When sibling conflicts become extremely aggressive or violent, this has been associated with problematic consequences for children's well-being and relationships outside of the family. For this reason, many parents are concerned about sibling conflict and the best ways to intervene. Research suggests that parents play an important role in supporting siblings' ability to develop empathy and to resolve issues constructively. For example, when parents are trained to

mediate sibling conflicts (i.e., help children understand each other's perspectives and come to mutually agreeable solutions), children are more effective at resolving issues on their own. Younger siblings become empowered to play an active role in negotiations, and in turn, older siblings are more likely to consider the goals and emotions of their younger counterparts.

Broadly speaking, when parents interact with siblings, it is important for them to avoid engaging in differential treatment and indiscriminately favoring one child over the other. Rivalry for parents' love and attention is evident from the first days of sibling relationships. The birth of a new sibling is often a challenging and stressful time for older siblings, who may exhibit a range of positive (e.g., affection, interest) and negative (e.g., clinginess, distress) reactions to this event. As children get older, rivalry also appears in other forms. For example, children frequently tattle on their siblings and react in jealous ways when parents give more attention to their brother or sister. When children view their parents as engaging in consistent favoritism, this has been linked to poor-quality sibling relationships, particularly if children view the favoritism as unfair.

In conclusion, the sibling relationship is a multifaceted and rich context for children's development, providing a natural laboratory for children to learn how to get along with significant others in their social worlds.

SIBLINGS AND PLAY

Siblings are often children's first play partners since about 80% of Western children have a brother or sister with whom they are close in age. The sibling relationship is an important context for young children's learning and development because in the early childhood years, siblings spend more time with each other than with parents or other children. Sibling relationships are also affectively intense, involuntary, and lifelong relationships. This relationship is characterized by both reciprocal (equal and returned) interactions such as during play and conflict and also by complementary (hierarchical) interactions that define teacher–learner interactions. Reciprocal interactions, particularly play and prosocial exchanges, are important for children's development and by age 3, siblings strongly prefer to play with each other rather than with their parents.

Play is considered a critical context for facilitating young children's language (e.g., vocabulary, narrative skills), social-cognitive (e.g., understanding others' perspectives) and social (e.g., sharing, affection), fine motor (e.g., dexterity, eye–hand coordination), creativity (e.g., alternative solutions), and problem-solving (e.g., conflict resolution) skills. During play, young children focus on the means (i.e., process) and not on the ends (i.e., product); thus, for example, they are more interested in the process of mixing colors while painting than in producing a painting of a specific house or person. Play provides opportunities for experimentation and flexible thinking, whether it is drawing with colored markers, building a tower out of blocks, or creating a pretense scenario. The social aspect of play is of particular importance; since children like to play together, the opportunities for joint

problem solving, learning to understanding another's point of view, resolving disagreements, experimentation, and coconstruction of pretense scenarios are endless.

What makes siblings such attractive play partners for one another? Siblings know each other very well because of their long and coconstructed history of growing up in the same family; thus, they are intimately aware of each other's preferences, shared knowledge about the world, and styles of interacting. Siblings often take great pleasure in playing together, especially in coconstructing pretend scenarios; these shared experiences can be used as the foundation for children's imaginative thinking.

Because of their knowledge of the younger sibling's skills and interests, older siblings can initiate and engage their younger siblings in play through a variety of strategies such as suggesting a play theme, demonstrating how to construct a city from blocks, scaffolding and building on their own and their sibling's ideas for creating pretend scenarios, and also responding in friendly and warm ways to the sibling's initiation of play ideas and actions. Employing these kinds of strategies not only invites the younger sibling to play; they are also effective in sustaining play episodes for long periods of time. In return, younger siblings have a role in maintaining the play interactions by imitating the language and actions of their older sibling and by using simple verbalizations to enhance the play (e.g., making animal sounds when playing with farm animals). While older siblings are more likely to initiate play episodes than younger siblings early on in their relationship, over time younger siblings become more active and equal play partners as their language, cognitive, and collaboration skills improve. Siblings who are more collaborative in their play and who seem to be "in sync" with one another are less likely to engage in disputes and controlling behaviors.

The focus on social pretend play is important because this activity requires siblings to work together to coconstruct and agree on a scenario by negotiating the roles, characters, actions, and story line to create a narrative. This is a process that

clearly requires sophisticated language, cognitive, and social skills. In addition, siblings must learn how to resolve disagreements and to take the perspective of their play partner, not always an easy process for siblings because of their age differences. Although sibling dyads differ in the degree to which they like to engage in pretend play together, many children spend long hours in this form of play, and those who do show a greater social understanding of the world compared with siblings who engage in less frequent pretend play. This social understanding is evident in the kinds of language that siblings use in their play, specifically references to others' thoughts (e.g., believe, think) and feelings (e.g., happy, sad). Use of this kind of language is associated with greater perspective-taking skills in children. When children are cognizant of how their sibling thinks and feels about the world, they can also spin a pretend scenario that includes references to what the pretend characters are thinking and feeling and thus enhance their joint understanding of the pretense.

Further, sibling dyads that engage in frequent pretense employ quite sophisticated negotiation strategies that facilitate joint play such as assigning roles, transforming objects (e.g., changing a roof piece into a mud flat for pigs), suggesting play themes ("Let's pretend . . .") and are more likely to use rich descriptive language (e.g., "upside down valley"). Siblings can create typical pretend themes defined by the characteristics of the play props, for example, having the "farmer" feed the cows hay, as well as developing creative themes that move beyond the props' characteristics and add a new element, such as pretending that a hurricane is blowing down the trees and barn. When siblings propose creative pretend themes, they are more likely to engage in object transformations that change the identity of an object to add to the richness of the scenario, for example, by indicating that a block is a piece of pizza. Sometimes siblings are more interested in the physical characteristics of the play props and how to set them up (e.g., building a train track or setting up a village) than in coconstructing a typical or creative pretend scenario.

In sum, the context of pretend play is important for the development of children's flexible thinking and creativity as well as their narrative skills, and the sibling relationship provides rich opportunities for these developments and to just enjoy the pleasure of playing together.

SLEEP

Sleep is defined as a period of relative inactivity where the body's senses and voluntary muscles are inactive. This entry examines current themes around sleep and young children, including how sleep contributes to healthy growth and development, the phases of sleep, and factors affecting sleep.

Phases of Sleep

Sleep has two distinct phases: non-rapid eye movement (NREM) or dreamless, quiet sleep that is divided into four mini-stages of increasing

depth; and rapid eye movement (REM) or active sleep where vivid dreaming occurs. In newborns, 50% of sleep is REM sleep. As children age, however, the percentage of NREM and REM sleep changes. By 4 months, approximately 40% of sleep is REM sleep and by 1 year, 25% of sleep is REM. Eventually, children match the adult average of 20% REM sleep.

Sleep and Health

Sleep is recognized as vital for maintaining good health. During sleep, the body produces new bone and tissue and repairs or restores what is damaged in the body when awake. Lack of sleep in young children is associated with a range of disorders including behavioral and mood difficulties, obesity, lower academic performance, and growth problems. For children with attention-deficit/hyperactivity disorder (ADHD), improvements in sleep result in higher academic achievement scores and healthier peer interactions. The consequences of poor sleep can be long lasting. Ongoing or cumulative sleep deficiency is linked to an increased risk of heart disease and high blood pressure in later life. Recent research findings indicate a strong relationship between infant sleep position and sudden infant death syndrome (SIDS). Placing infants on their back to sleep is the number one way to reduce the risk of SIDS. Additional SIDS-reducing sleep practices include ensuring that the sleep surface is firm and safety-approved, that soft objects and toys are kept out of the sleep area, and that overheating is avoided.

Factors Affecting Sleep

Age

Sleep requirements vary according to age. Most newborn infants spend 70% of each day, or 16 to 17 hours, sleeping. This decreases as they grow. By the time an infant is 8 weeks old, he or she is sleeping more during the night and less during the day—although there are cultural influences associated with the expectation that infants sleep throughout the night. By 4 months of age, infants

adopt adultlike sleep patterns, spending most of their daytime hours awake and nighttime hours asleep. Not all children follow this sleep developmental trajectory, however. Between 10% and 20% of young children fail to establish stable sleep patterns. Infants who are reported to have sleep problems at 8 months are more likely to be poor sleepers throughout their early childhood years.

Temperament

Temperament is an individual's biological reaction to environmental situations or stimuli. Infants with a challenging temperament (characterized by high levels of intensity, distractibility and/or fussiness, and a low level of adaptability) are more likely to have problems with sleep. Temperamentally challenging infants sleep less both during the day and at night. Young children who were reported by parents as having an easy temperament with low distractibility and high adaptability demonstrated increased sleep. A caveat to these results is in order since most studies of temperament use parent self-report measures and are subject to reporter bias.

Separation Anxiety

At 8 or 9 months of age, infants begin to understand that their primary caregivers exist even when they are not with them. This marks an important stage of healthy emotional development and it is typical for infants during this stage to cry when put down to nap or sleep. They are anxious about being left alone. While the first signs of separation anxiety generally start at the end of the child's first year, this phase of development can last until his or her second or third birthday. Separation anxiety can interrupt even the most established sleep routines and schedules but this regression fades as the child grows. Caregivers can help by offering reassurance to the child, by letting the child know when the caregiver is leaving (not sneaking out), and/or by playing peek-a-boo. Games such as peek-a-boo or jack-in-the-box help the infant understand that when something is out of sight, it comes back. If this otherwise normal phase of development continues beyond 6 years of age, it

may be a sign of a separation anxiety disorder and may require treatment to resolve.

Culture

Culture helps shape underlying beliefs, values, knowledge, customs, and norms about sleep. This in turn influences parenting practice. Euro-American parents are known to encourage the cultural practice where children sleep at scheduled times in their own room. Asian parents, in contrast, are more likely to promote bed sharing throughout childhood. In some rural communities in Africa, infants are carried around throughout the day and sleep in slings on the back of their mother or a female sibling. At night, they sleep in close contact with their mother. No effort is made to schedule the infant's sleeping pattern, and sleep typically consists of short naps throughout the day and night. Unlike their Euro-American counterparts, at 4 months of age these infants sleep no more than 4½ hours at a time. This divergence in sleeping practice is informed in part by the culture in which the child is reared.

The Sleep Environment

The sleep environment can significantly impact sleep patterns. For example, studies indicate that exposure to light can affect how well children sleep. Having a television or other media in the bedroom can disrupt the body's natural day-night rhythm and should be avoided. To encourage sleep, the environment should be quiet, cool, and relaxing.

SMART START (NORTH CAROLINA)

Smart Start is North Carolina's comprehensive, community-based initiative to improve the early care and education (ECE) system. Serving children under age 6 and their families, the main long-term goal of this initiative is to ensure that all children are healthy and prepared to succeed in school. Smart Start has been a leading example of the "reinventing government" movement wherein government sets performance objectives and provides flexibility to communities in how to meet them. Smart Start empowers communities to make their own decisions about how best to improve their ECE system. Other states and communities have used the initiative as a model when designing new early childhood initiatives.

Advised by early childhood experts and backed by major business leaders, both Republicans and Democrats, then-Governor Jim Hunt and the North Carolina General Assembly established Smart Start in 1993. An initial \$20 million of tax revenue was appropriated to fund 12 pilot Smart Start counties, one per congressional district. A system of allocating the funding to counties was established that considered both needs and existing resources for young children. A competition for funds was held. Each county, or group of counties applying together, had to collaborate by establishing a local nonprofit 501(c)3 partnership before applying. Twelve "pioneer" partnerships were funded in 1993 and over the next 4 years, as the annual funding increased, 81 local partnerships encompassing all 100 North Carolina counties were funded. The highest level of funding was achieved in the 2001 fiscal year, \$250 million.

Local partnership boards are comprised, by statute, of a diverse mix of community members who work collaboratively to plan and fund programs that will best meet the needs of their community. The nonprofit North Carolina Partnership for Children (NCPC) provides statewide leadership, technical assistance, and oversight for Smart Start.

In the first years of the project, state guidelines were loose and counties were encouraged to take

different routes to the ultimate goal of school readiness. However, after a few years, the NCPC developed a list of core services. Eventually, the legislature mandated that at least 30% of Smart Start service funds be spent on child care subsidies for low-income parents and 40% on other activities related to center- and home-based child care such as quality enhancement and professional development. The remaining funds could be spent on health and family support activities.

The initial legislation funded a statewide Smart Start evaluation conducted between 1993 and 2003 by a team of researchers from the Frank Porter Graham Child Development Institute and the schools of education, public health, and maternal and child health at the University of North Carolina at Chapel Hill. Evaluation goals included documenting the process, determining whether Smart Start-funded efforts improved the quality of early childhood programs, and assessing whether Smart Start benefited children and families. Because hundreds of different activities and interventions across the state were implemented as part of Smart Start, the evaluation team developed a post hoc logic model based on the delivery process of the many activities and their intended outcomes. Activities fell into four broad categories of services related to child care quality improvement, family functioning, children's health care, and increased or improved interagency collaboration. Most of these activities had implicit, if not explicit, short-term goals in the pursuit of the long-term goal of school readiness.

Guided by this systems change model, the evaluation efforts focused substantially on access to and quality of early childhood education programs, and children's health, language, and social outcomes. Other studies focused on families and the collaboration process. The studies used rigorous research methods whenever possible; both qualitative and quantitative analyses were conducted. Over 10 years of evaluation, 35 different studies were completed. Because local partnerships focused at least 70% of their funds on child care issues, a few of these studies are described below.

A variety of local activities addressed the availability and quality of center- and home-based child care programs. Each year the numbers of centers, teachers, and family child care providers that participated in these activities increased and the number of children affected by these activities increased. In addition, 8,900 new child care spaces were created with Smart Start funding.

The quality of early childhood education also improved. Donna Bryant, Kelly Maxwell, Michele Poe, and Karen Taylor (2003) observed 180 randomly selected ECE classrooms using Thelma Harms and Richard Clifford's environment rating scales and showed that quality increased steadily and significantly across four assessment occasions from 1994 to 2002. Compared with 1994, in 2002 more than twice as many classrooms scored in the high range on the quality measure. Another study showed that the quality of center-based care was significantly related to the number of local quality improvement activities in which the centers participated and, within a partnership, to the amount targeted to quality improvements. Ellen Peisner-Feinberg, Kathleen Bernier, Bryant, and Maxwell (2000) found a similar positive association between family child care quality and participation in Smart Start quality initiatives. In 12 partnerships that significantly increased the numbers of high-quality programs in their county, key-informant interviews conducted by Taylor and Bryant (2002) revealed the variety of strategies these partnerships employed, including grant programs for purchase of quality enhancement materials, on-site customized technical assistance delivered by consultant/educators, linking subsidy reimbursement amounts to quality improvement, and support of college education for teachers and family providers.

Did Smart Start achieve the goal of improving children's readiness for school? By prospectively following into kindergarten 214 preschoolers (4-year-olds) who had attended ECE centers that had participated in extensive Smart Start quality improvement activities, and comparing them with 294 classmates who had attended non-Smart Start centers, Maxwell, Bryant, and Shari Miller-Johnson (1999) found significant differences between the two groups. Smart Start children entered school

with significantly higher vocabulary scores and more positive teacher ratings of their social skills; they were also 50% less likely to have behavior problems. These differences were seen even after controlling for poverty. The study's pediatrician, Jonathan Kotch (2000), compared the same two groups of children, and found that those who attended Smart Start centers were significantly more likely to have a regular source of health care than children who had not (90% versus 82%). A study of 512 children in 120 classrooms linked a center's participation in Smart Start quality improvement programs to higher classroom quality and also linked higher classroom quality to higher scores among children on assessments of literacy and numeracy skills, as reported by Bryant and team members (2003). It was this study that provided policy makers the most convincing support for the positive effects of Smart Start.

The evidence supports the view that Smart Start is an innovative and effective model that many other states and communities have followed when designing new early childhood initiatives.

SOCIAL CLASS EFFECTS ON DEVELOPMENT AND LEARNING

Social class is defined as a system of stratification within society that separates groups and individuals on the basis of their relationship to capital. Although there is variation in how class is categorized, often the upper class refers to those who own the means of production; the middle class are those white-collar workers/professionals who invest in capital and who have control to a degree over the working-class/blue-collar wage workers, who are often grouped with the poor. Oftentimes, social class is aligned with income and educational levels. Because of structural inequities within society, the social class hierarchy is influenced by factors such as race/ethnicity, gender, sexuality,

language/national origin, and (dis)ability. Because these factors are intertwined, early childhood research often adopts an intersectional approach when discussing social class, and a similar approach is adopted in the following discussion. In this entry, effects of social class on children's development are described, as are the historical, theoretical, and practical tensions experienced by researchers and educators studying childhood through a social class lens.

Overview

Social class is associated with equity because, as sociologists such as Pierre Bourdieu, Ellen Brantlinger, Annette Lareau, and Carol Vincent have described, families and children are positioned hierarchically based on their social class status. This affects child care, early education, and schooling. Social class is an especially important construct in early education. That is because *habitus*, which is defined as the dispositions, attitudes, and habits of mind that an individual internalizes as he or she experiences social interaction and social class, is shaped at home and at school in the early years. There exist different life trajectories for various social classes. The most limited outcomes are for the poor and working classes, who are systematically marginalized in society and who may be disadvantaged not only by class but also because of their race/ethnicity. While poor and working-class groups have strengths such as resiliency and strong, resourceful families, it is a myth that it is common for poor and working-class individuals to break into the upper class. While early childhood education has long played a role in identifying and remediating the effects of social class to produce improved outcomes for poor and working-class children, debates continue about how the opportunity gap among children and families can be dismantled.

Historical and Contemporary Perspectives

Researchers have long been concerned with finding and remediating the effects of poverty in

young children through preschool. Two such turn of the 20th century interventionists include Maria Montessori and G. Stanley Hall. The 1930s to 1960s saw research linking various kinds of “sensory deprivation” and “cultural incompetence” among the poor to a lack of exposure to White, middle-class experiences that could be provided in early education. Since the 1960s, researchers have sought to uncover specific variables within individuals from different social class and racial/ethnic groups to provide clues on how to remediate the deficiencies caused by disadvantage. This was part of a larger project that sought to prevent and remediate barriers for the poor and working classes.

In the 1960s, the popular media promoted hypotheses regarding a culture of poverty existing in urban areas. This rhetoric implied that African American families were the “problem” in need of remediation. This discourse was derived, at least in part, from the well-known research of the anthropologist Oscar Lewis, who in the 1950s and 1960s developed his theory that there was a true transnational, cross-generational culture of poverty that was an adaptation and reaction to the marginalization of the poor in capitalist society. At this time, the federal government responded with a number of social programs designed to fight the War on Poverty, including Head Start. Prior to Head Start, a number of research programs studied ways in which to remediate the effects of social class. In the early 1960s, the Perry Preschool project, for example, implemented the HighScope curriculum with low income, African American students. Researchers found that over the years, there were higher graduation rates, less delinquency, and less special education placement among the children who attended Perry Preschool.

During the Johnson administration’s War on Poverty, Head Start was conceived as a federal government intervention that could eradicate poverty in the United States. While consistently underfunded since its inception in 1965, Head Start has provided part-time readiness-oriented preschool to poor and minority children. While Head Start programs have conceived of parent involvement in

different ways, many programs have had parent empowerment and advocacy components.

While the knowledge gained in these early projects suggested progress toward addressing the deficits created by class, 4 decades after these initial intervention projects, social class inequalities remain marked. For example, research in 2002 by Valerie Lee and David Burkam used Early Childhood Longitudinal Study (ECLS-K) data to show widespread cognitive differences in young children even before kindergarten entry, with poor and working-class children more likely to attend underresourced schools and experience cognitive delays than their middle-class counterparts. Overall, research in the 2000s has shown a more complicated picture regarding the nature of class and its effects on education.

As shown through recent research by Pamela Bennett, Amy Lutz, and Lakshmi Jayaram, school settings have the power to erase opportunity gaps between the social classes, but because of the complex effects of parenting logics, financial resources, and the institution of schooling, schools may ironically contribute to inequities because they do not provide the quality and types of activities and instruction that children who attend middle- and upper-middle-class schools receive. Similar findings are specific to preschool settings, for example in a 2013 report by Tran Keys and his colleagues. Furthermore, Brantlinger, Allison Griffith, and Dorothy Smith have shown that the members of the middle class, and especially mothers, are positioned by the educational system to advocate for pedagogies and practices that benefit middle-class children while excluding poor and working-class children. One persistent example in early childhood education is the practice of *redshirting*, defined as delaying kindergarten entry for middle-class boys with summer birthdays. As Beth Graue has described, this is a “gift of time” for the middle class in which the curriculum is intensified for all children, and poor and working-class children who do not have the opportunity for redshirting fall further behind their peers. Kindergarten should not be delayed for any children because children of all social

classes who are held out are more likely to receive special needs labels later on.

Theories Informing Views of Social Class in Early Childhood

Inherent in the chronology of early childhood education are particular theories of child development and childhood that have changed over time. Early childhood education has long been informed by developmental psychology. Jean Piaget's theories reflect findings about White, middle-class children, and the milestones derived from his theories do not adequately address social class. This is true especially when the intersections of culture and race/ethnicity are taken into account. Another important body of research comes from cognitive psychology and emphasizes the importance of ages 0 to 3 especially in promoting cognitive growth. The downside of such psychological theories is that they often locate deficiencies within individual children and their families. Early childhood researchers may alternatively use critical and sociocultural theories to understand how social class matters in communities. For example, they may apply Bourdieu's scholarship emphasizing the connections among economic, social, cultural, and symbolic forms of capital that structure the class hierarchy.

Critical theorists such as Valerie Polakow and Beth Swadener have been articulate in explaining how policies and other structural issues cause poverty and contribute to inequitable education and care for children and families. These issues are important to the role of early educators in shaping better practices that address social class and other inequities and support a perspective that sees children from the poor and working classes as "at promise" rather than "at risk."

While sociocultural and critical theories have greatly expanded understandings of social class effects, unfortunately, research and practice have sometimes followed the disproven notion that the White middle class is in itself an ideal culture. An example of this is the "culture of poverty" theory articulated by Oscar Lewis in the 1960s

and reinterpreted by Ruby Payne in contemporary times. Early education programs have at times emulated these monocultural views rather than advocating critical and multicultural approaches to teaching. This has, in turn, perpetuated deficit views of children and families based on class and race.

Practices

High-quality early education can erase opportunity gaps for children from poor and working-class backgrounds. The mainstream early childhood field relies heavily on the National Association of Early Childhood Education (NAEYC) accreditation model to support developmentally appropriate practice (DAP) frameworks. DAP is considered to be a high-quality model that many programs use in framing their philosophies and practices. However, debate continues in the early childhood field regarding the roles of culture and context in informing theories and practice. The meanings of quality in early education should continue to be considered. This has particular importance for the kinds of experiences offered to poor and working-class children, who may indeed be culturally different, not because they come from a culture of poverty but because there is an intersection of social classes and the multiplicity of cultures that exist in our diverse society. Recognizing children's varied cultural backgrounds and addressing structural disadvantages that lead to educational bias by class, race/ethnicity, and other identity categories are like two sides of the same coin; both are needed in early childhood education.

Public policies have changed parental roles in early education, often supporting a "parent involvement" model that is difficult for poor and working-class parents to implement. For example, such a model may encourage gendered middle-class forms of involvement like baking cupcakes and volunteering in the classroom for short time blocks during the school day. New ideas from Patricia Snell and Joyce Long reconceptualize parents' roles to enable parents to define their own involvement, and parents' involvement is interrelated with

their identity development in relation to school. By strategically helping parents overcome their own negative experiences with schooling, parents can then become more involved because they no longer are fearful of schools. These new lenses on families help early childhood educators develop more nuanced perspectives on social class, equity, and families.

Among national programs that provide targeted supports, Early Head Start is now an important intervention alongside Birth to Three and Head Start. Each of these reforms may support low-income children and children with disabilities, but access is limited. Since the mid-1990s, individual states have begun to implement various forms of prekindergarten. In several states, universal prekindergarten provides sometimes free readiness instruction to 4-year-olds and sometimes 3-year-olds regardless of income level. This programming relies on the research by Karen Schulman and Steven Barnett that the middle class may be priced out of preschool along with the poor and working classes, and that the middle class too may be at an educational disadvantage in the early years. With the Pew Charitable Trusts and President Obama's support, prekindergarten continues to expand. Prekindergarten may be the next frontier for exploring possibilities for erasing the opportunity gap.

SOCIAL PLAY AND COGNITIVE DEVELOPMENT

Children live in a social world. From birth, they initiate an examination of their world. Through their development (infant, toddler, preschool, primary age), children explore and attempt to understand their social and physical surroundings. They progressively discover their growing community and ultimately consider themselves to be citizens. This entry explores the role of play in young children's self-discovery and knowledge acquisition; specific attention is given to the stages of social play that structure children's early lives.

Young Children and Knowledge Acquisition

Young children have to learn about themselves, their world, and their relationship to it. They test their knowledge on their physical and social world to obtain feedback from their outside world and distinguish the limitations between themselves and their immediate world. Young children acquire the knowledge and capabilities that they need to both function in their daily life and lay the groundwork for future learning. They basically manage their physical world and practice their knowledge concerning physical devices by touching, listening, or observing. They inspect objects and experiences in their current surroundings. Children discover, study, and try to understand the natural objects and situations that are around them. For instance, on the way to and from school, children observe everything that is in their environment. Then, in their classroom, they act out their observations. They will naturally express their worries with others and materials in their surroundings. Children constantly seek solutions to inquiries like "How?" "How does it work?" "How did it get there?" "How do you know?" When children play, they are, as Melanie Peter (2003) observes, "learning how to do it while doing it" in order to engage more meaning-

fully in a social world and heading toward a higher level of social knowledge and understanding (p. 21).

Children need to have access to all sources of information that is simple, clear, and accurate. They also need to be provided with authentic and vicarious experiences that can assist them in finding answers to their questions. Authentic experiences can include trips and personal contacts, whereas vicarious experiences can include pictures and books. Any type of experience needs to be carefully chosen and created to make sure that they are overall all-inclusive to help young children recognize details, apply the knowledge they learned in their play, and develop their understanding when they interact with others.

Young children observe the individual's behavior to understand its *meaning*. The effects of social behavior based on the situation provide meaning to the behavior, such as when children play. For instance, dramatic play fosters the children's personal and social learning. They begin to understand their social world when they act out roles the way they perceive and understand them. In dramatic play, young children interpret their social world, family, school, and community and role play their beliefs about their world, which is part of social play. When young children assume roles that represent those from their social world, they learn to get along with children with different perspectives. For instance, a child may convey "No, I don't want to be the mommy! I want to be the daddy!" In this situation, children discuss, negotiate, compromise, agree, and resolve disagreements among themselves, although children are at different social stages.

Stages of Social Play

The children's social play is vital in their development of pretend play. Current progressive points of view concentrate on the impact of the social context on their cognitive processes. This theoretical scheme includes those classifications of social interaction that have an impact on the children's cognitive development. As Lev Vygotsky maintains, such social interactions are enriched in the

children's pretend play. Their play behavior and social competence develop with age. Children who typically participate in play appropriately, solve problems, share information, and usually develop friendships easily, including with those children who meet for the first time, become friends when they play with each other. Children join social play when they (a) discuss their pretend play plans (such as "Hey, the Ninja Turtle just bashed you!"), (b) engage in pretend play, or (c) combine their solitary pretend play activities.

Since 1932, researchers have studied the children's stages of social play. Mildred Parten initially classified a progression of stages of social play: Three-year-olds participated in *unoccupied play* (not playing at all), *solitary play* (playing alone), or *onlooker* (observing other children play). Four-year-olds usually engaged in *parallel play* (playing side by side with others). Five-year-olds typically participated in *associative play* or *cooperative play* (playing with other children). Cooperative play was considered to be more developed than solitary play while parallel play was a transition from solitary play to cooperative play.

During the last 4 decades, several researchers, including Kenneth H. Rubin and Olivia N. Saracho, have questioned the stability and validity of Parten's social stages of play. They have found that young children display several stages of play for different reasons throughout their development. Some children are independent thinkers and prefer to play alone or alongside others, whereas others prefer to engage with their friends in associative or cooperative play. In her 2002 study, Saracho found that the children's personality has an impact on their sociability. Social children who like being with others participate in parallel, cooperative, and associative play; whereas less social children participate in solitary play. Parallel play (children playing alongside their peers) implies that children are becoming more advanced in their play, which may lead into more complex, interactive play. Frequently children can switch between solitary and cooperative play behaviors. In an earlier study, Saracho identified the following four characteristics in the children's play behaviors:

1. Frequency of play—how often children engage in play
2. Communication of ideas—how often children communicate (e.g., using words, pictures, gestures) their thoughts during play
3. Social participation—how often children engage in Parten's (1932) stages of social play: solitary, onlooker behavior, parallel, associative, and cooperative
4. Leader or follower—how often children initiate play

Play is vital in the children's social and cognitive development. During play, they learn the meaning of play and its function in life, civilization, and culture. Children's play helps them to understand the world around them and play what they see. They notice how their community members function such as going to the office, driving a bus, working at stores, or attending parties. Children act out these roles with their different problems and solutions. Their play permits children to test out new ideas without being frightened of failing. Children learn about social norms during pretend play when they engage in imaginary situations that offer them social opportunities and complications. They understand their make-believe experience and develop intellectual interpretations that affect their attitudes, behavior, and peers' point of view. Children assume different perspectives in their play and develop their social competence as they represent shared environments that are meaningful to their peers. Pretend play assists young children to examine and test their understanding of familiar social situations in imaginary contexts where they develop their own cultural patterns. During play, children exhibit their development of understanding of different objects and situations as well as their feelings and relationships about their peers in different situations as they act out important emotional pressures and themes. They learn how to cope with unconscious pressures. Pretend play gives young children the freedom to experiment with roles, resolve conflicts, and solve problems. It also helps them make sense of the world and be

able to negotiate meanings with their peers. When children participate in social pretend play, they encounter a joy that expresses their creative development throughout life. Social pretend play also helps children create an imaginary world that provides boundaries for the children's experiences. They recognize the life mysteries that they observed in intellectual and aesthetic areas. It includes both the social and physical elements that interact with each other and the children's individual developmental levels.

Many consider play, acting, and thought to be analogous, because they are processes that young children use (a) to test reality, (b) to free themselves of their anxieties, and (c) to control their situation. Imaginative play, make-believe play, fantasy play, dramatic play, sociodramatic play, symbolic play, and pretend play are related phenomena. All phrases represent play in relation to "pretending" or the application of symbols that "stand in" for that which is real. For instance, a child acts out being a dog and another child is the owner; a puppet talks for a child; or a stack of blocks symbolizes a cave for bears.

In the American culture, where ethical values endure, play is thought of as being a frivolous activity, without any valuable effects. Early childhood researchers and educators support the cultural belief that learning emerges only from work. They support play by referring to it as "child's work." In fact, play can be enjoyable, exciting, and imaginary and still have important educational values for young children.

SOCIAL REFERENCING

Social referencing is a process of social influence whereby one's interpretation of a novel event is inferred from others' reactions to it. Although social referencing occurs among adults, researchers have paid considerable attention to infants given their broad social naïveté, meaning most situations are new to them and they must determine how to respond. Through social referencing, the emotional signals of others provide important interpretive guidance to infants, especially when confronted with new or ambiguous situations. This is one of the first behavioral and affective self-regulation strategies available to infants. In addition to providing them with important information about novel situations, it reveals infants' sensitivity to the behavior and affect of others and serves as a cornerstone of social and cognitive development.

Using social referencing, infants rely on facial, vocal, and behavioral cues of others—attachment figures in particular—to understand the emotional meaning of a situation. Classic examples can be seen when infants look to caregivers when approached by a stranger or after falling down. Thus, caregivers provide an emotional gauge for infants, who regulate their responses accordingly.

Understanding infants' use of social referencing is important for developmental, clinical, and theoretical reasons. Social referencing explains how infants gain crucial information about the physical and social worlds. This information is especially critical as they gain motor independence and are more likely to be in situations of risk (e.g., approaching stairs or a dangerous object). In understanding the relationship between an event and another's emotional response to it, infants come to regulate their own affect and behavior. Thus, social referencing is a simple but powerful self-regulation strategy used in the first year of life.

Research on Social Referencing

Joseph Campos and Craig Stenberg argue that social referencing is a biologically organized process for communicating important emotional messages like threat and joy. In support of this idea, social referencing has been observed in nonhuman primates including rhesus monkeys and chimpanzees where facial expressions communicate affective messages, separating rough and tumble play from aggression, for example. Of evolutionary relevance is the finding that children look longer at parents' expressions of fear than of happiness, suggesting the greater signal value of fear in communicating critical information about risk. The adaptive advantage of social referencing is that it allows infants to learn about threat and risk vicariously via caregivers' affect, bypassing the need for firsthand experience.

According to Campos and Stenberg, Mary Klinnert, and Tedra Walden, referencing is marked by two key features. First, it occurs under conditions of ambiguity. Second, the affect of the referent influences the infant's emotional and behavioral

responses toward the event. These affective messages may be actively solicited by the infant or may be inferred indirectly from the referent's facial, behavioral, and vocal reactions to the event. Caregivers are the most likely referents, but infants will also reference unfamiliar adults who are part of unfamiliar events, as though infants see those persons as having specific expertise about the novelty and how to respond to it. Numerous studies with infants show robust effects of social referencing on infants' affect and behavior toward a wide variety of novel situations other than fear or threat, including pretend.

Historically, most social referencing studies use the visual cliff paradigm, in which infants who are new to crawling or walking are placed in an ambiguous motor situation (i.e., having to assess whether they can descend a sharp drop) to determine whether the infant's decision can be influenced by parental facial and/or vocal cues. As a result, younger infants who are not close to crawling or walking have received little attention in the social referencing research, although anecdotal observations suggest that they too are keen observers of parental affect. Walden proposes that although younger infants may not intentionally refer to their parents to interpret ambiguous situations, parents provide these emotional messages anyway, and infants tend to match their affect as a result. Recent research has shown that 5½-month-olds and 6-month-olds are more likely to touch a novel toy that has been associated with positive emotional cues delivered by an adult, and that 6-month-olds direct more gazes at an event subsequent to observing a parent smile and laugh at it. Such findings suggest that younger infants' behavior, though not their affect, toward a novel stimulus or event is influenced by the affect of others toward it.

Thus, although young infants may not solicit emotional information the way older infants do, they do pay close attention to caregivers' unsolicited emotional cues, looking longer and more frequently at caregivers when they provide emotional information about an event. These studies suggest that social referencing emerges from young infants'

tendency to pay close attention to novelty as well as to others' affective expression toward it, so that they eventually understand that others can serve as emotional referents from whom they can solicit affective guidance and respond accordingly. Thus, social referencing appears to emerge from infants' preference for novelty that by 6 months gives rise to information seeking and affect sharing, and by the second half of the first year results in joint affect sharing toward events.

Clinical Relevance

Since young infants learn to respond to situations by mirroring the emotional expressivity displayed by parents, social referencing may have clinical relevance, particularly with regard to emotion regulation. This is especially important in understanding how maternal depression, for example, may influence infant emotion regulation and expression. Edward Tronick's classic studies of the still-face paradigm show that 3-month-old infants whose mothers simulate depression exhibit emotional negativity and reduced smiling. This may be a direct result of the infants' use of mother as an emotional referent and could suggest a point of intervention with depressed or highly anxious mothers and their infants. In fact, infants of depressed mothers are less likely to reference them, perhaps because those dyads disengage.

Atypical Development

Children with developmental delays do not exhibit the same tendency to rely on social referencing. Specifically, children with autism fail to process faces differently from objects, which at least partly accounts for their diminished reliance on social referencing. A theory of mind is also directly related to social referencing, as both require the ability to perceive social cues including facial expressions. Thus, the presence or absence of social referencing can be useful as an indicator of other developmental processes.

SOCIAL SKILLS AND SCHOOL SUCCESS

Social skills are skills developed and practiced through engaging with others and include appropriate interactions and use of societal norms. Children must have opportunities to learn in positive environments that support curiosity, problem solving, and social interactions. Children need time to laugh together, wonder with their teacher, and get lost in books for the joy of the story. A sense of belonging and opportunities to share ideas with peers are necessary for children to feel successful in the classroom. Children need to be able to construct understanding through physical interaction with materials, play with peers, trial and error, and moving their bodies. This requires teachers to slow down, allowing children to think

and explore like typical children of their age. This entry examines the importance of developing children's social skills and the role social skills play in their school success. It then considers some of the consequences of not placing social skills, such as collaboration, at the center of the curriculum.

Overview

Since the early 2000s, there has been a very distinct shift of priorities in teaching children. Many schools have moved from early classrooms focused on play and building relationships to a drill and skill environment in an effort to meet testing requirements connected to funding sources. This has resulted in classrooms that overlook the following essential understandings about how young children learn:

- Children need meaningful experiences in learning to make sense of processes and to build understanding.
- Children need social relationships to learn important concepts such as cooperation, negotiation, compromise, and empathy.
- Children need to be able to make mistakes in all domains and disciplines in their efforts to grow and learn.
- Children need to move their bodies and explore the arts while learning.

As children are coached through social development and peer relationships, the complexities are compounded by the fact that children are exploring and interacting with a variety of different personalities; what worked for successful interaction with one peer may not be effective with another. Positive social experiences lead to a secure environment that allows children to take risks, to feel capable in their efforts and trusting of their teacher, knowing he or she is there for support, guidance, and celebration.

Theory

The pragmatic approach, which was recognized by John Dewey in the late 1800s to early 1900s, is being largely overlooked today and is intended to

address practical matters of applying children's interests and natural curiosity to daily activities to maximize learning and social opportunities. Dewey's democratic ideals are reflected in the contemporary views of researchers such as Dan Gartrell, who identifies democratic life skills for building a community of learners. When practicing from this perspective, teachers build a trusting classroom where children know they belong, can make mistakes, and become problem solvers in creative and long-lasting ways. Many classrooms today fail to foster the interest and innate curiosity that Maria Montessori noted were essential for all young learners. Additionally, the drill and skill approach that is being implemented in many classrooms locks children's thinking in at the very lowest level of Bloom's taxonomy: *remembering*. When Benjamin Bloom identified the concept of mastery learning, he was referring to a learner moving from lower order thinking to higher order thinking, the goal of meaningful learning.

Intervention

Children need to be able to discuss and make sense of the tasks they are being asked to complete. A child who is able to explain how and why he sorted and classified items into groups is expressing an ability to analyze. A child who is given the opportunity to explain a sequence of events is able to evaluate a situation. In sharing and discussing these ideas, children may learn from one another, and their shared ideas may help others "see" a concept in a new or different way, broadening perspectives and deepening understanding. The use of hands-on sensory learning tools, providing project opportunities, working in pairs and groups, and having choices in the classroom are all ways that social experiences can be enhanced for young learners.

Class meetings offer countless opportunities for teachers to model and children to practice discussing and expressing opinions, problem solving and mutual respect, and sharing and caring. Through meetings, teachers can explain and demonstrate concepts while scaffolding skills in meaningful ways.

As schools cut back on recess, the arts, and social engagement, many children are overwhelmed by the external pressures of academics and assessment. When teachers are encouraged to build positive classroom communities, modeling caring and concern for everyone, time is spent getting to know each other and children are encouraged to work together. As members of this community of learners, children feel a sense of belonging and caring about one another. When they are able to make mistakes, whether through attempts at decoding in reading or negotiating with a peer, children grow by practicing important skills, while being coached and supported by their teachers. Teachers need support and concurrence for creating healthy environments from administrators who understand child development and trust teachers to know their young students well while providing opportunities to build positive relationships, practice interpersonal skills through role playing, trade book topics, and engage in authentic conversations.

Classrooms where children feel they belong, where they feel safe, where they can trust adults to guide them, and where they are provided with activities that are engaging produce young learners who are highly interested, curious, and motivated and will therefore persist through challenging tasks.

Notably, many businesses today search for employees who are able to work and collaborate with others, yet these skills are being overlooked in many classrooms. If schools do not recognize the need for social learning, students are unlikely to gain the skills necessary to attain success in this important area. Schools have a responsibility to help children become successful citizens equipped with all the skills, including all the social skills, needed to excel in the future.

SOCIAL SKILLS ASSESSMENTS

Social skills have been defined in many ways. Broadly, social skills are interpersonal responses that allow children to adapt to their environment in order to initiate and sustain interpersonal relationships through verbal and nonverbal modes of communication. There are a number of social skills assessments available for young children that have been widely used to identify individual social deficits, guide decision making in the selection of social skills programs and services, and evaluate intervention or treatment outcomes. Because *social skills* is a broad term that encompasses several specific skills and behaviors that span various domains of social functioning (e.g., acceptance, communication, engagement, friendship, play, reciprocal interaction, etc.), assessing social skills in young children may be challenging. Many social skills assessments incorporate contextual factors, so that the varying function and rules of social behaviors across situations and social partners can be appropriately captured. The purpose of this entry is to review a broad array of social skills assessments that are frequently used in research, clinical, and school settings. These assessments vary in administration, completion, and method and include parent and teacher rating scales, self-report measures, behavioral observations, Q-sorts, and sociometric ratings.

Rating Scales

Parent and teacher rating scales are commonly used to assess children's social skills across the home and school settings. The benefit of rating scales is that they are easy to use and time efficient. The following are comprehensive and widely used rating scales. The Preschool and Kindergarten Behavior Scales (PKBS), now in its second edition, is a norm-referenced multirater rating scale that measures the social skills and socioemotional behavior problems of preschool and kindergarten children ages 3 to 6. The PKBS has two domains: Social Skills, comprising Social Cooperation, Social Interaction, and Social Independence; and Problem Behavior, comprising Externalizing Problems and Internalizing Problems. Another widely used rating scale is the Social Skills Improvement System (SSIS). The SSIS is a multirater (i.e., parents, teachers, and students) assessment of general social behaviors for children 3 to 18 years of age. The SSIS yields three categories: Social Skills, Problem Behaviors, and Academic Competence. Lastly, the Social Responsiveness Scale is a parent- and teacher-rated measure that assesses reciprocal social behavior that has been used to distinguish children between the ages of 4 and 18 years with a pervasive developmental disorder from those with other psychiatric conditions.

Self-Report Measures

Although less frequently used, self-report measures of children's social skills provide information about a child's perceptions of his or her own social competence. Self-reports generally ask children to report their thoughts and opinions about their social behaviors and relationships as well as how they would act in various social situations or interactions. The SSIS, reported above, has a self-report version.

Behavioral Observations

Behavioral observation is another method that is frequently used to assess children's social skills. Of the various methods, behavioral observations are the most ecologically valid method of assessing

children's social skills as they capture social behaviors in the setting in which they naturally occur. Typically, behavioral observation entails a well-defined behavior (e.g., engagement, peer initiations and responses, etc.) to be observed or the use of a coding system to classify observable behaviors and trained independent observers who observe children across a set period of time within a natural setting (e.g., home, classroom, playground, etc.). Within these settings, behavioral observations may provide important information with regard to the frequency and range of social behaviors. One frequently used observation system is the Playground Observation of Peer Engagement (POPE). The POPE is a time-interval behavior coding system that examines children's social engagement and communicative behaviors with peers on school playgrounds. The POPE is designed for children 4 to 12 years of age.

Q-Sort Methodology

The Q-sort methodology differs from traditional paper and pencil measures as it allows raters (i.e., parents, teachers, school staff) to rank in order—from most characteristic to most uncharacteristic—a set of descriptive items to which scores are assigned. The Social Skills Q-Sort (SSQ) permits descriptions of individual children's repertoire of social skills in order to create one comprehensive social skills profile. The SSQ consists of a set of 100 descriptive cards of children's social skills, to be arranged or "sorted" into nine piles whose designations range from most characteristic (pile 9) to least characteristic (pile 1). Each item on the SSQ is scored in terms of its placement (piles 1–9) in the distribution (e.g., each of the five items in pile 9 received a score of 9; each of the eight items in pile 8 received a score of 8, and so forth). Subsequently, the items are correlated with the criterion means to generate one total SSQ score.

Sociometric Ratings

Sociometric ratings are another useful methodology for assessing peer acceptance, rejection, and

popularity. Sociometric ratings provide a robust picture of children's informal classroom peer groups, or social networks. Generally, sociometric ratings entail peer nominations, where children list classmates that they prefer and do not prefer to hang out with as well as peer ratings of children they see hanging out in groups. Sociometric ratings have been used with children ages 4 to 18.

The social skills assessments provided in this entry represent a sampling of the vast number of methodologies used to assess social skills for young children. The selection of the appropriate assessment will depend on a number of factors including the social skills of interest, the particular context, and data collection procedures, among others.

SOCIAL STUDIES TOPICS

Young children typically think about their needs and gradually learn to care about the needs of others. An important aspect of development is for children to learn and interact with people around

them, first family and then community, and to care about the needs of themselves and others. Usually, the first people young children come into regular contact with are their family members, and their home makes up their immediate surroundings; soon after they begin to interact with their community. Children come to understand how elements of their community, such as school, faith-based institutions, government, and civic organizations influence them. It is therefore the responsibility of families and educators to help young children learn about their community and their role in it. Integrating social studies into young children's school experience is the best way for them to learn and experience community.

Models have been advanced to explore the significance and extent of communities that young children relate to. Urie Bronfenbrenner's ecological systems theory model has been applied to advance the understanding of how children experience family and communities. This model explains that children's understanding of communities begins with their personal experience through their relationship with their families. This understanding expands to include community aspects such as their school, neighborhood, and other places beyond. As children observe and experience their environment, they begin to comprehend nature and their place in it. They need support in order to experience their community in positive ways.

Research

Young children understand communities in different ways depending on their age. For infants, their community consists of family, caregivers, and peers. They understand and learn their environment by engaging in it through play, exploration, and interaction. Preschoolers' engagement with their environment is broader. Their community expands to include their school, including the teacher and their peers. They have the opportunity to expand their understanding of community through working together with others and solving problems together. The teacher's role is to encourage preschoolers to think outside of themselves.

Kindergarteners' understanding of their environment includes their ability to make friends and follow instructions and classroom rules. They are better than preschoolers at communicating their needs and wants. Understanding their environment includes learning concepts in the classroom through discussions, writing, and drawing.

Primary-school-age children understand their environment in various ways, including through problem solving. They are better able to understand others and differences between people. At this age, their drawing and writing are more precise, making it possible to clearly express their understanding of their community. Children are able to understand their immediate community when teachers involve them in working with others in developmentally appropriate ways.

Children develop their sense of identity in part based on their relationships with their families. They learn how their families value them and their place in their families based on the attention they get from family members. The home experience impacts children's involvement in communities outside the home.

The Teacher's Role in Promoting Community

In order to build community, teachers need to model the meaning of community and how children are to relate to people in it. Teachers need to put into consideration various aspects that will help them successfully foster knowledge of community. Aspects such as a welcoming and safe classroom environment, routines and procedures, wall arrangements, transitions, seating arrangements that reflect diversity, classroom meetings, and interpersonal relationships encourage opportunities for communication and self-expression in respectful ways.

Classrooms that do not emphasize community building are not able to tap into children's ability to learn and grow as community members. Teachers can involve young children in authentic learning opportunities and activities in the following ways:

Planning and setting expectations allow children to work better as a classroom community when following given sets of expectations rather than classroom rules. Classroom expectations or plans provide a positive classroom climate so that children focus on what they should do rather than what they are not supposed to do.

Class meetings provide children a safe environment to practice basic interpersonal skills such as respect, communication, and valuing of different opinions.

Promoting responsibility to each other through following various routines and doing tasks and chores individually and as a group allows children to learn responsibility.

Teamwork and mutual support activities are ways for children to learn social competence, as Mary Jalongo notes in her 2006 article “Professional Development: Social Skills and Young Children.” Social competence is a basic human skill meant to establish positive relationships. Through such activities they are able to experience a sense of belonging, being appreciated, and being valued.

Establishing a sense of belonging helps children feel a part of the classroom. This can be achieved through helping them know what to expect from their teacher and throughout the day. A predictable environment helps children feel safe in their classroom community. Displaying their work around the room and walls not only reflects diversity in the classroom and community but also helps children experience a sense of belonging.

Involving community helpers in order to broaden children’s sense of community allows children to interact with community members not only to learn but to practice aspects of human interaction already learned in the classroom. These community helpers include police, firefighters, medical personnel, and postal workers. Additionally, children should be given opportunities to practice classroom chores such as cleaning and distributing supplies.

In their 2015 book, *Social Studies and Young Children*, Eucabeth A. Odhiambo, Laureen E. Nelson, and Kent Chrisman point out that understanding and celebrating diversity is a valuable opportunity to talk about differences and similarities. Occasions such as birthdays and holidays are opportunities to celebrate differences and similarities. When children share with their classmates their differences through displaying their work, pictures, and fingerprints, they are able to view individual difference in a positive light.

Children are born into a community setting. In order to grow and integrate into the community, they need to develop the skills required to successfully relate to their families and community. The family working together with the school can foster these skills through authentic, developmentally appropriate classroom activities.

SOCIAL-EMOTIONAL COMPETENCE

Social-emotional competence is an important developmental milestone that influences all aspects of children’s lives. The development of social-emotional skills occurs throughout childhood and

is strongly linked to school success, both academically and socially. Emotional competence consists of a child's comprehension, expression, and regulation of emotions. As children mature, they learn to apply their knowledge of emotions to social situations in order to regulate their display of emotions in accordance with societal expectations. Therefore, emotional competence and social competence are interdependent. One definition of *social competence* is success with peer interactions and is typically measured through peer acceptance. Children are more likely to be accepted by their peers if they master important social skills such as perspective taking, conflict resolution, and reciprocity in order to achieve social goals. Although researchers explore many predictors for social-emotional competence, there are three overarching criteria that are essential, particularly in educational contexts: (1) self-regulation, (2) conflict resolution, and (3) positive peer relationships. Individual differences (e.g., biological and environmental factors) influence the extent to which children learn, practice, and master these three components.

Criteria for Competence

Self-Regulation

Self-regulation is mastered when children are able to manage and control their emotions and behaviors. First, they learn to identify basic emotions (joy, sadness, anger, fear) through facial and body expressions. As they gain generalized experiences with these emotions, they develop knowledge of the causes for the emotions that then serve as cues to assist them in understanding the social situation. If children can identify the emotion and talk about the emotion, research has found, they are more likely to be socially competent. Over time, they learn societal rules that determine when and where emotions can or cannot be displayed and that distinguish between acceptable and unacceptable behavior. These rules are socially and culturally constructed and differ according to where a child is raised. Children are socialized

to conform with these rules, and expectations for compliance increase as they age and learn. The goal of socialization is for children to feel good about themselves as they learn to behave according to society's rules.

Parents are considered to be the primary source of socialization in early childhood. First, they provide emotional and social experiences for young children. Infants and parents develop a pattern of interaction in which they initiate and respond to each other's emotions in a reciprocal manner. There is theoretical support and research evidence that the quality of parent-child interactions is predictive of a child's interactions with others throughout childhood. Children who are emotionally secure within their parent-child relationship are more likely to achieve positive academic and social outcomes. Parents also determine who enters the social world of their young children and where their children spend time, such as in an early childhood education program. In later stages of childhood, children have the capacity to choose their social partners, and peers become a very important influence. Although peers may be equally inept with regard to social skill development, they may have a greater expertise about same-age peer group norms and expectations than parents. This is particularly salient for children from immigrant families. Second, parents model emotional expressiveness for their children, informing them about the nature and causes of emotions. Research has found that children learn to modulate their own emotions in response to their expectations for their parents' reactions and as a result these reactions are highly salient in the development of emotional knowledge. Third, parents socialize their children through discussions of emotional and social behaviors. Parents typically "coach" their children about societal expectations regarding appropriate and inappropriate emotional displays and social behaviors. Children internalize social rules and apply them to their interactions with peers. However, because they continue to come across unfamiliar situations and are still learning self-regulation, conflict often erupts between peers.

Conflict Resolution

Conflict resolution is an important skill to learn that is dependent on self-regulation. Very young children approach conflict in simple and impulsive ways; they use aggression, seek assistance from an adult, or passively turn away from conflict. As children mature, they learn to use verbal strategies to solve conflict. Children with friends are less aggressive and have fewer conflicts. In other words, children who manage conflict well are more likely to be accepted by their peers and to be considered socially competent. Girls tend to use more relationship-oriented strategies to resolve conflict while boys tend to use more assertive, self-centered strategies. It is important to note that these findings may be primarily relevant to cultures in which the defined gender roles correspond with these strategies.

Children eventually learn to modify their conflict resolution strategies to achieve social goals. For example, if the goal is to maintain harmony and continue play, they may be more likely to concede during a conflict. Social goals are influenced by the level of friendship (friend or nonfriend), the environmental resources that are available (space, materials, activities), and the purpose of the conflict (personal rights, object possession). Conflict is considered to be a necessary component of social development and should be allowed to manifest in order to provide children with the opportunity to practice their resolution strategies and achieve success within their peer relationships.

Peer Relationships

One of the most important developmental tasks for children is to create and retain positive relationships with peers. These peer relationships are built on a framework of interactions and experiences together that can be characterized as equal with regard to competence and power. Infants identify peers as social partners with smiles, vocalizations, and gestures. Toddlers engage in cooperative games and conflicts moving toward social pretend play during the preschool years. Some toddlers and *most* preschoolers have friends. Researchers define *friendship* as a mutual

preference for shared interaction, play, and positive affect. Children learn to regulate their emotional responses within interactions to coordinate social play with others. They have to communicate their affection and desire to create a friendship with each other in order for play to develop into a mutual preference. This skill is dependent on emotional understanding and an ability to read the cues of a social partner. Some believe that children's accuracy in perceiving themselves and others depends on the amount of practice they have had in social situations. Others believe that deficits in social perceptions are based in cognitive development. Both theories are likely to be true in that children who have difficulty with social cognition skills are less accurate in social perception, are more likely to be rejected, and have fewer opportunities to improve their skills.

Individual Differences

There are biological and environmental protective factors that contribute to individual differences in social-emotional competence. For example, children who are physically attractive have been found to have higher levels of peer acceptance and more mutual friendships. And, as mentioned earlier, children raised by parents with appropriate parenting strategies co-construct secure attachments and are more likely to develop positive peer relationships during their childhood than children with insecure attachments. There are, however, also biological and environmental risk factors that lead to individual differences. Biological risk factors such as temperament, autism spectrum disorder, shyness, or physical disabilities such as vision loss are just a few examples that influence social and emotional development. Environmental risk factors might include child maltreatment, poor-quality early childhood education programs, and low socioeconomic status (SES).

Biological Risk Factors

Temperament is defined as a biological basis for individual differences in affect, activity, and

attention levels that can be observed from infancy and that remain relatively constant throughout development. Some children react intensely and negatively to various aspects of the environment while others display mild reactions or varying reactions. Over time, and with maturation and experience, children develop coping strategies that modify their reactions to fit within the environment, and these adjustments are referred to as personality. Temperament may have both direct and indirect effects on social development. For example, high reactivity and poor regulation are directly predictive of the development of aggressive behavior. On an indirect level, children with different temperaments elicit varying responses from others and seek out different types of environments, thus determining the level of practice they gain in the social world.

Children with autism spectrum disorder (ASD) struggle with understanding and regulating their emotional responses appropriately according to the demands of societal norms and expectations. Their reactions do not comply with the social rules that other children have learned and this leads to problematic interactions and, at times, peer rejection. These children may actively isolate themselves from others. Shy children similarly may withdraw from others but as a result of fear and anxiety when faced with new social situations or peer judgment. They may desire to play with other children but lack approach skills. Typically, they will observe other children at play without participating. Children with a visual loss may also experience isolation because they are unable to interpret the social cues that are found in facial and body expressions. They miss the subtle shared experiences that explain rules and conventions related to play. Research has found that children with a visual impairment have lower rates of peer interaction, higher rates of adult interaction, and higher rates of solitary play than same-age peers without disabilities. In each of these examples, a factor that lives within the child impacts his or her perspective of emotions and social knowledge.

Environmental Risk Factors

Risk factors can also be externally introduced into a child's life through the environment that the child experiences, thus resulting in individual differences. Inappropriate parenting practices such as abuse or neglect have been correlated with insecurity in the parent-child attachment relationship and poor peer relationships. Maltreated children are more likely to be aggressive or withdrawn in social situations. Similarly, children in poor-quality early childhood education programs are more likely to be aggressive. Although poor-quality care is not equivalent to the emotional trauma of maltreatment, children's experiences with peers and teachers in settings that lack safety, supervision, or a positive emotional climate do not provide adequate opportunities to learn positive social skills. Fewer practice opportunities lead to the perpetuation of immature resolution strategies, such as aggression, during conflict. Children whose families are economically disadvantaged also lack opportunities to play with same-age peers due to an increased risk for exposure to violence in their neighborhoods and reduced safety in playing outdoors. Research indicates that children in lower SES families engage in less complex play than same-age peers in middle-SES families. The collective outcome for children with biological or environmental risk factors is that they have less practice with social situations, and the interactions that they do have are often challenging. Yet, children differentially respond to risk in varying and dynamic ways that can lead to isolation or resilience.

Key Factors in Promoting Social-Emotional Competence

Emergent emotional skills complement and facilitate social abilities. Children begin to express their feelings appropriately, regulate their emotions, and learn social rules for behavior, providing a foundation for appropriate interactions with teachers and peers in preschool, kindergarten, and beyond. They are initially socialized by parents and later by peers. Social-emotional competence develops gradually in an interdependent manner but can be influenced by biological and environmental factors that lead to

individual differences. Regardless of differences in biology or environment, the most important component is frequent opportunity to practice perceiving the emotional states of others, testing various social responses, and gaining social and emotional knowledge that can be retained and applied to new situations until, eventually, competence is achieved.

SOCIAL-EMOTIONAL DEVELOPMENT

Social-emotional development is the domain in which children grow in their understanding of their emotions and of the emotions of others and learn to create positive relationships with those around them. Children are able to identify their own feelings and be sensitive to the feelings of others, regulate their emotions and behaviors, demonstrate empathy, and form relationships. Current thinking about children's social-emotional development emphasizes the importance of relationships and the complexity of the contexts of each child's life.

For much of the past century, a major goal of early childhood has been the socialization of children, as they grow in their emotional well-being and learn to negotiate interactions with others in their world. With recognition of the tremendous growth that takes place in the first years of children's lives, there is now an emphasis on all developmental domains. Specific focus on cognitive development is a result of recent pressures for children's academic performance. However, social-emotional development remains important because it contributes to children's cognitive development. Additionally, social-emotional development plays a role in the development of children's prosocial behavior, which is at the core of anti-bullying and character education programs in schools and classrooms. Although the goal of socialization has often been, and still is, explained in terms of a young child's future success as an adolescent or adult, social-emotional development is now also recognized as a vital goal for the present well-being of each child.

A Contemporary Approach to the Knowledge Base

The knowledge base of social-emotional development is a synthesis of theory, including both historical foundations that retain meaning and validity and new perspectives from contemporary research that extend and strengthen our understanding. The

body of traditional theory that continues to guide us and new insights gained from advanced research lead us to relevant and practical work with, and on behalf of, young children and families. What we have learned in our work with children and families, or in other words, “the wisdom of best practices,” is enhanced by the application of this dynamic body of theory and research.

The social and emotional worlds of children are inextricably linked in a shared developmental domain although, in some writing, they appear as separate areas of knowledge, inquiry, and application within disciplines. These varying perspectives only serve to enrich our knowledge.

Major Theorists and Theories on Social-Emotional Development

There are several theories that serve as historical foundations in the social-emotional development of young children.

Attachment theory, developed by John Bowlby, addresses the nature of the emotional bond between infant and parent or caregiver that occurs beginning in the early days or weeks of a child’s life. Attachment continues to develop through interaction and mutual affection over the course of the first 2 years of life. In her further study of attachment, Mary Ainsworth defined types of attachment as *secure* or *insecure*. This theory remains valuable to our understanding of the beginnings of social-emotional development in young children and has significant implications for work with infants.

Erik Erikson’s psychosocial theory of development continues to resonate with contemporary thinking, as each of his life stages presents critical dichotomies, or conflicts that need to be resolved, that are related to children’s social-emotional development. Within his life-span stages of psychosocial development, the first four, *trust versus mistrust*, *autonomy versus shame and doubt*, *initiative versus guilt*, and *industry versus inferiority*, apply to young children from birth through age 8. As we continue to explore the importance of relationships in

social-emotional development, it is helpful to note that the adults in children’s lives are also engaged in their own conflicts in their critical life stages. Teachers and others working with children and families may consider the “fit” between needs of children and adults in their own stages.

Jean Piaget’s theory of cognitive development also addresses children’s social-emotional development. His stage theory includes social-emotional developmental expectations linked to cognitive development, such as object permanence in infancy and aspects of play and interaction with peers in the preschool years. Additionally, he identified three stages of children’s moral development: premoral, moral realism, and moral relativism. While Piaget’s theory of children’s construction of knowledge is still widely accepted, aspects of his stage theory have been called into question. In the social-emotional domain, children are capable of perspective taking and empathy at earlier ages than in Piaget’s stages.

Lev Vygotsky’s sociocultural theory continues to have extensive implications for social-emotional development. Learning through social interaction is the underlying theme in his theories of *internalization*, of learning from an adult or a more capable peer, and of the *zone of proximal development*, or ZPD, the distance between what a child is able to do independently and what the child is able to do with help. This theory emphasizes the child’s potential for development rather than the development that he or she has already achieved. Vygotsky (1978) commented on how children’s play leads to development: “In play, a child always behaves beyond his average age, above his daily behavior; in play it is as though he were a head taller than himself” (p. 102). His sociocultural theory reflects current perspectives on context in children’s social-emotional development.

Contemporary Theoretical Perspectives

Several other theories on social-emotional development stem from more recent research.

Bioecological Systems Theory. Developed and refined by Urie Bronfenbrenner, it has relevance for contemporary and emerging theoretical perspectives. This theory explains children's social-emotional development in terms of relationships and context. Interactions across and between nested systems that take place beyond the family context affect children's development. Bronfenbrenner's theory includes elements that are a function of social-emotional factors: *process*, regular and ongoing interactions within the individual's immediate environment; *person*, characteristics of individuals that can influence processes over time; *context*, the five systems of the original ecological systems model (the *microsystem*, *mesosystem*, *exosystem*, and *macrosystem*, and the historical time of the *chronosystem*); and *time*, those things that happen in an individual's day or lifetime, as well as in the historical time context of the chronosystem.

Neurological Perspectives and Applications of Brain Research. Advances in neurobiology and their implications for children's development have brought about new ways of thinking, have challenged our assumptions, and have provided affirmations of early theory. An understanding of neurological development and of the process of the strengthening of synapses in the brain allow us to identify *windows of opportunity*, or optimal times, for certain types of brain development. During these windows of opportunity, teachers and caregivers can offer appropriate experiences to children in order to support their development in the social-emotional and other domains.

The Research-Theory-Practice Dynamic. In an example of this process, Robert Pianta has extended attachment theory to teachers and caregivers, with his research on classroom climate and teacher child interactions. He has reenvisioned Bowlby's theory in terms of "attachment networks" and alternate attachment figures, other than parents. This concept can also be connected to the research on resilience in children, as resilient children persist in their efforts to develop a relationship with a "caring other."

New Discourses. The importance of relationships in social-emotional development is reaffirmed with emphasis on the bidirectionality of children's relationships with parents and other family members, teachers, siblings, and peers. Variations in social-emotional development and the effects on children's early school experiences have entered the discourse, along with the context of temperament and the ability to form positive relationships, as well as home language, culture, and ethnicity. Inquiry from a feminist perspective is suggested as a framework for the examination of relationships in the lives of children.

Research Initiatives. Widespread concern about children's development in the early years has led to large-scale research projects and reports, many of which have been federally funded in the United States with data from the National Center for Education Statistics. A study of the science of learning by the National Research Council Committee on Early Childhood Pedagogy resulted in the 2001 publication *Eager to Learn: Educating Our Preschoolers*. Another example is a 2003 report from the National Research Council, *From Neurons to Neighborhoods: The Science of Early Childhood Development*. That these large studies have been funded and conducted is evidence of the national interest in children in the early years. This work has led to new insights and yet more questions about children's social-emotional development.

Best Practices for Enhancing Children's Social-Emotional Development

Having opportunities for play and experiencing positive relationships with peers and adults promotes social-emotional development among children in diverse and inclusive early childhood settings. Teachers can create and maintain caring classrooms, engage in themes of care in the curriculum, integrate the arts (drama, music, dance, and visual arts), and practice an anti-bias curriculum. Learning and using a language of kindness and respect for others gives each child a space to grow socially and emotionally.

Initiatives in many classrooms and communities address a range of social-emotional issues. Conflict resolution, bullying prevention, responding to tragedy and natural disasters, poverty and food insecurity, post-traumatic stress syndrome identified in children and adults, and social media and screen time are but a few. For those working with infants and toddlers and their families, understanding each child's temperament will support social-emotional development. Identifying the young child's temperament type allows adults to provide appropriate ways to help the child negotiate the experiences in their world. Meaningful family engagement is a powerful factor in classrooms that fosters children's social-emotional development. Knowing that all developmental domains are interrelated, teachers can be intentional in supporting social-emotional development along with cognitive, language, physical, and aesthetic learning.

Contemporary Insights and Questions

An increasing awareness of social-emotional development and its role in children's cognitive development calls for the joining of voices of practitioners and researchers seeking empirical evidence. Social-emotional development is seen as more than "just getting along in the blocks area." Another avenue for investigation is the examination of the power of relationships and what they look like. There are parallels in the lives of children living in the contemporary world of the 21st century to the children Robert Coles depicted in a series of studies of children beginning in the 1950s, published in several volumes as *Children of Crisis*. Postmodern and critical theory perspectives will provide new insights on children's social-emotional development. Questions remain: What will support the social-emotional development of each child now and in the future? What do children think and say about their world and how do they respond?

Implications for research, practice, and policy include an awareness among policy makers and others that children's social and emotional development

has the potential to address concerns about cognitive development and academic achievement and about the need for peaceful schools and classrooms.

SOCIOCULTURAL THEORY

Sociocultural theory is an umbrella term for a range of theories that offer social and cultural lenses through which to understand development and learning. Over the past 20 years, sociocultural theories have been adopted in early childhood education in an attempt to move forward theoretically from the earlier theorizing of developmental psychologists. Sociocultural theories include a range of concepts and ideas developed from Russian psychologist Lev Vygotsky's legacy that have implications for education. In different ways, these theories tease out the mutually constitutive relationship existing between people, activities, institutions, and cultures. In this entry, Vygotsky's legacy and selected key concepts are overviewed. The entry further examines how sociocultural theories have recently diverged into two main branches: cultural-historical/activity theory and theories of participatory learning.

Vygotsky's Legacy

Vygotsky's theories of development arguably provide the most enduring legacy to sociocultural theories. Vygotsky studied the processes of development that enable humans to make meaning from appropriate culture. While Vygotsky did not study children under 7 years, his theoretical concepts have been extrapolated for early childhood by subsequent scholars and underpin many

contemporary theories of development and approaches to education.

Vygotsky believed that learning leads development and occurs in several ways simultaneously on a number of levels: ontogenetic (life span development, the focus of developmental psychology), biological and sociocultural phylogenetic (evolutionary changes in humans and cultures that impact on individual development), microgenetic (actual learning by individuals in contexts), and cultural-historical (dynamic changes across time). Vygotsky viewed development as proceeding through a series of crises resolved dialectically (i.e., resolution of contradictions and tensions), rather than age or stage related. Vygotsky's work therefore also incorporated a mesogenetic (historical and temporal) dimension in studies of development.

Within sociocultural approaches, the individual and the context together form the unit of analysis. Vygotsky discussed the role of people and cultural tools (e.g., language, semiotics/signs/symbols, artifacts, resources, and equipment), institutions, activities, and events in mediating learning and teaching. Vygotsky's focus on speech/language as the most important cultural tool, from individual words to dialogue as a unit of meaning making activity to focus on in research, brought to prominence the importance of relationships and interactions that mediate learning. Therefore when applied to education, his theory holds that knowledgeable peers and adults in multifaceted roles support children in their exploration and construction of new understandings, knowledge, and skills and their development of dispositions toward learning. In early childhood education, consideration of language as comprising nonverbal gestures and communications as part of building the relationships that support meaning making has also been a vital area for research.

Vygotsky's early writing centered on concepts such as personality, motivation, emotions, fantasy, and imagination as sources of development. Vygotsky viewed play, and particularly sociodramatic play, as a major source of development. In particular, he believed play was important in developing children's potential to behave and act above

their current age. Children's play provides a way for them to take part in the social life of the adult world before their skills are adequate for real participation. Imagined situations, symbolic actions, scripts, roles, and rules provide the mediational means for such play as children use cultural tools to interact with peers and adults. As children act out understandings of real-life behaviors (e.g., what parents do), they assume the actions, language, thinking, and emotions of the human roles they are imagining and in which they are engaging. For example, successfully playing house or playing family requires that children have knowledge of family roles and responsibilities and intersubjectivity with play partners. Play can also be an innovative expansion of understandings, a way that children both practice and transform knowledge. Vygotsky's work maintained that education should be authentic, that is, it should be relevant to the daily life and practices of a child in a community or culture. For example, he maintained that children should learn to read and write in the context of their play, rather than be taught letters in isolation of authentic language.

The *social situation of development* refers to the way internal developmental processes are determined by external conditions. These are more than resources and contexts surrounding children; they are the affordances and conditions drawn upon in self-motivated ways to actively extend learning and understanding and resolve crises and contradictions that arise. In this way, understanding meaning making is about more than thinking and speech; it involves thinking and communication more broadly. Thinking develops through motives and goals integral to social and institutional activities and practices.

Given that understanding activity was central to understanding development, Vygotsky proposed that each stage of development had a *leading activity*—an activity prominent in children's motives that could also be drawn on by adults to promote development. Emotional interactions with caregivers were viewed as the leading activity of infants; object-centered joint activity with adults, the leading activity of toddlers; sociodramatic play

the leading activity during early childhood (3 to 6 years); and learning at school was children's leading activity during middle childhood.

Externalization and internalization explain the relationship between intermental and intramental processes of learning. This is the basis of Vygotsky's (1978) often-cited statement:

Every function in the child's cultural development appears twice: first, on the social level, and later, on the individual level; first, *between* people (*interpsychological*), and then *inside* the child (*intrapyschological*). This applies equally to voluntary attention, to logical memory, and to the formation of concepts. All the higher [intellectual/cognitive/mental] functions originate as actual relations between human individuals. (p. 57)

Put simply, the zone of proximal development (ZPD) has been understood as a way of assessing what a learner can do with support rather than what he or she is able to achieve alone. More broadly, it describes developing psychological capabilities in children; therefore, applied to education, it explains the difference between children's unaided performance and performance with assistance. ZPD was used as a metaphor to represent a zone where children's everyday understandings interact with conceptual knowledge provided by mediators of learning, such as teachers. Further, the ZPD can therefore be viewed as a dynamic, creative zone during mediated interactions. In this final view, the zone can be viewed more as a zone of potential development. This may open up possibilities for responsive pedagogies within the zone and actions by adults to revisit and expand opportunities that extend children's learning.

Mediation is a relational concept that acknowledges that humans use cultural tools, symbols, practices, and artifacts to learn about the world. Explicit mediation refers to the constraints and affordances of ideas and activities from people or cultural tools for human thinking; implicit mediation refers to the role of social and inner speech as communication that assists learning. Therefore,

mediation also connects societal and cultural processes with human cognition.

Vygotsky described how children learn *everyday concepts* through participation in everyday experiences without explicit instruction. Three phases of everyday concepts occur simultaneously in young children's first meaning making attempts. Gradually, through play, language, and later instruction in school, children develop and recontextualize everyday concepts into *scientific concepts*. The task of early childhood education might then be viewed as to provide opportunities to re-create, represent, and extend the kinds of everyday experiences children enjoy, through provision of culturally appropriate curricular and pedagogical approaches.

Perezhivanie acknowledges the mutual interplay of perceptions, cognition, and emotions in meaning making/subjectivity and lived experience. While Vygotsky encouraged the consideration of many aspects of the social situation of development and meaning making that follow, he considered *perezhivanie* as a holistic phenomenon contributing to human consciousness and personality development, unable to be separated into constituent parts.

Cultural-historical theory is a term used recently by some early childhood researchers to integrate and build on the work of Vygotsky and later Russian scholars, such as Vasily Davydov (particularly his theory of learning activity based on the dialectical method of ascending from the abstract to the concrete), Aleksei N. Leont'ev (objects and activities as central to development), Alexander Luria (a focus on neuropsychology), Evald Il'enkov (internal contradictions as the driving force of change and development in activity systems), and Dimitry Leont'ev (a focus on explaining notions of meaning making). Cultural-historical theory proposes a theoretical conception of development anchored in participation in cultural practices and societal conditions. This approach pays simultaneous attention to children, adults, and cultural practices and activities in analyzing children's development and learning. The theory highlights motives, demands, intentions, goals, and engagement.

Mariane Hedegaard tackled the notion of stages common in developmental theory. She replaced this with the word *trajectories* to examine in a more complex manner the kinds of crises Vygotsky linked to points in development that are prompted by participation in the practices and interactions of cultures. In this way, a richer conceptualization of development is posited, and children can be viewed as competent and capable participants and active contributors to their development.

Development of Sociocultural Theories

An abundance of sociocultural theories has developed with different disciplinary foundations, emphases, and terminology. These theories have helped theory and research move beyond psychological generalizations to understanding culturally specific beliefs and practices important to children's development. Overarching names for the plethora of sociocultural theories include *activity theory* and *cultural-historical activity theory* (CHAT), *social constructivism*, and *participatory learning/intent community participation*. These theories have developed Vygotsky's ideas by enabling researchers to focus on sociocultural activity as the unit of analysis and emphasizing the learning inherent in any context. Simultaneous attention to children, adults, and cultural practices and activities occurs in analyzing children's development.

Activity theory was an early response to Vygotsky's ideas that was consistent with its Marxist foundations in collective consciousness and the historical, social, and economic conditions of cognition and action. Activity theory goes beyond explaining individual development to draw attention to the mutually constituting nature of activities, actions, and systems in different settings as influences on development. Yrjö Engeström and colleagues have developed this approach by focusing on the complexity of human activity in differing contexts (exemplified in teams and workplace organizations), and the multiple interpretations of activity that different tools and practices encourage. In addition, they usually include a formative intervention in their research design, that is, a

research-based professional learning and development element that works alongside professionals to examine and improve practices.

Activity theories emphasize practical activities and cultural practices in shaping learning. Three generations of activity theory have evolved. The first generation derived directly from Vygotsky's ideas about tools, signs, and mediated action to consider dialectically individual and social experience as the unit of analysis. The second generation focused on an object-oriented activity system as the unit of analysis. Analyzing collective activities is very demanding as these represent complex phenomena in constant change and contradictions. For example, a child at play is connected to the activities provided in the educational environment; both of which are related to teacher(s), parents, child peers, and other contributing objects, activities, and people. Therefore, the third generation of activity theory has identified multiple interacting activity systems, connected by partially shared objects, as the unit of analysis.

Many key concepts underpin activity theory: activity system/s as the unit of analysis, multi-voicedness, historicity, contradictions as a driving force of change in activity, expansive cycles as possible forms of transformation in activity, object, mediation, ZPD, sense and meaning, internalization and externalization, transformative agency, double stimulation, ascending from the abstract to the concrete, and formative intervention. Each of these is a major theoretical concept to develop and use in research that aims at improvement, transforming and emancipating people in their collective activities. These concepts have been applied in developmental work research (DWR) that has explored the activities of a range of institutions, including schools and early childhood education settings.

Cultural-historical activity theory (CHAT) is often used as a term interchangeably with activity theory. However, it appears to have developed from activity theory and cultural psychology. Cultural psychology is a systems model that views context as the most important system contributing to making meaning as a focus of development. It

posits that specific descriptions of culture are vital to understanding explanations of development and children as active learners within cultures. CHAT also has a temporal dimension whereas activity theory is somewhat synchronic. CHAT's focus is on the incorporation of the collective into the individual consciousness and on studying ways externalizing features become internalized through processes of mediation. In this way, it seeks to explain how people become competent, knowledgeable, and able to act on their worlds. Hence the concept of agency has become important. This development is central in Anne Edwards's work on relational agency that has been taken up in early childhood education as educators proactively negotiate and share expertise with other professionals they interact with in their work with children and families.

Participatory and Community Learning

Participatory learning theories highlight ways everyday activities in communities and cultures contribute to development. These theories draw on three branches of sociocultural theory. The social-constructivist branch of sociocultural theory highlights adults and children engaged in pedagogical relationships whether their activities are designed to be educational or not. The activity theory branch emphasizes the culturally specific nature of the objects and practices with which children are involved. The cultural-historical branch ensures the perspectives of the participants, including adults, and the sociocultural contexts, motives, demands, and constraints of the activities and practices are respected during interpretation. Critically, participatory theories draw on sociological and anthropological disciplinary foundations alongside Vygotskian concepts for research approaches and analytical constructs. These theories have also served to move narrow understandings of culture focused on ethnicity and identity as influencing development to more complex and integrated definitions that intersect with these categories in particular contexts. These theories foreground the importance of recognizing

and building on children's family, community, and cultural learning and knowledge and therefore contribute to approaches to education that value these factors. Motivation is intrinsic to achieving real participation goals.

This work derives extensively from the research of North American scholars such as Luis Moll, Barbara Rogoff, and their colleagues. Although Vygotsky is credited with drawing attention to culture in learning, he did not provide a definition. Rogoff defined *culture* as accepted, routine ways of carrying out everyday activities and processes, which change over time due to shifting technologies and practices. These practices are often tacit and therefore both powerful and often overlooked for their importance. Culture has become a broad concept for attempts to help explain people's participation in overlapping cultural communities as they develop their own repertoires of practices—practices that are familiar and encourage individuals to approach learning in known ways and make connections between contexts. However, sociocultural theoretical explanations do so without implying that cultures are cohesive or necessarily share values and practices.

Participatory theories also emphasize the motivation children have to participate in activities valued by their families, communities, and cultures. Children participate intently to learn valued knowledge, skills, and practices in ways specific to their communities. Intent community participation highlights the cultural-historical and collective nature of learning. These theories highlight the dynamic patterns of interactions and engagements found in everyday life; some are followed, some resisted, and some transformed through participation to become expectations for the next generation.

Concepts such as legitimate peripheral participation, communities of learners/practice/inquiry, and intent community participation highlight that learning occurs informally in relationships and activities not necessarily designed to be pedagogical. These theories emphasize that development occurs through a process of participation in cultural communities that have different values, expectations, and technologies. Similar to other

branches of sociocultural theories, all learning and knowledge construction is situated, or otherwise understood as mediated by social relationships, activities, cultural tools, and practices. These mediating factors also change over time; thus, learning is viewed as a process of transformation of participation (i.e., as people participate in cultural practices, both the people and activities and practices change) that has personal, interpersonal, and cultural-institutional impacts.

Development is also guided by variations in goals that “prioritize learning to function within the community's cultural institutions and technologies” (Rogoff, 2003, p. 23). For example, different expectations of children occur as a result of different technologies and practices; Rogoff's work has highlighted that self-care and care of younger children occur at a variety of ages in different South American cultures, often much earlier than many Western countries might expect and in contrast with other non-Western countries and cultures where children remain dependent on adults until school age.

Rogoff and Moll's research in families and communities has done much to challenge deficit views of families and see them as rich in knowledge and capacity. One specific application is that of funds of knowledge (FOK). As a theoretical concept FOK values the everyday knowledge of families related to matters such as economics, household maintenance, literacy, and the arts, and further values the participatory relationships within which this knowledge is learned. Methodologically, FOK involves teachers visiting family homes to learn about the cultural activities and practices that encourage this knowledge. For example, children might observe a parent writing a shopping list or reading a recipe. In this way, children develop early knowledge of literacy embedded in specific family routines and practices. The pedagogical goal of a FOK approach is to recognize and incorporate family-based knowledge and expertise in educational settings in order to improve outcomes. In this way, participatory theories are able to begin tackling a political agenda concerned with power and structures that

resonates with the social justice imperatives common to early childhood education.

SOCIODRAMATIC PLAY AND SARA SMILANSKY

Preschool children often engage in the enactment of scenes pretending to be a mom, dad, baby, or superhero. This kind of play is described using various terms, including *dramatic play*, *pretend play*, *imaginative play*, *fantasy play*, *symbolic play*, and *role play*. When this kind of play happens with two or more children, it is referred to as sociodramatic play. In other words, sociodramatic play refers to pretend play in a social context. This entry examines the importance of sociodramatic play and pays specific attention to the theoretical and clinical contributions of Sara Smilansky. This

entry further outlines the characteristics of sociodramatic play and explores its developmental benefits. Finally, the entry examines approaches to sociodramatic play training.

Sara Smilansky and Sociodramatic Play

The term *sociodramatic play* was used and disseminated widely by Smilansky. Smilansky was a chief research psychologist in the Szold National Institute for Research in Behavioral Sciences in Israel and was also a professor in the Department of Psychology at the Tel Aviv University in the 1960s. She received a doctoral degree from the Ohio State University in clinical and educational psychology. Based on Jean Piaget's theory relating to play, Smilansky developed the four stages of play development, which is widely used in understanding children's sequential levels of play. This hierarchical stage model includes functional play, constructive play, dramatic play, and games with rules. Sociodramatic play is placed at a higher level of play development and was recognized as having cognitive benefits and maturity. Critics of the play scheme, such as professor Peter Smith at the University of Sheffield, criticize this hierarchical play stage model for a lack of inclusiveness of the scheme and argue that constructive play is not less mature than dramatic play.

Smilansky was interested in studying differences in sociodramatic play between children from higher socioeconomic classes and those from lower socioeconomic classes. She found that the children from disadvantaged homes often display a lack of sequence in their behavior, and showed repetitious and disconnected activities in sociodramatic play. She believed that training for sociodramatic play would be a way to help these children to be more flexible, creative, and elaborate in their behavior. Guided by her belief, she devoted herself to developing sociodramatic play training for disadvantaged children and conducted the first large-scale play training study. The training significantly improved disadvantaged children's play. Her play training is written about in detail in her book *The Effects of Sociodramatic Play on Disadvantaged Preschool Children*. The book was published in

1968 and has influenced further studies on dramatic play in the United States.

James F. Christie, a professor at the Arizona State University, researched and expanded Smilansky's play training in the early 1980s. Between the late 1970s and early 1990s, sociodramatic play gained considerable attention from early childhood researchers and psychologists in the United States. More recently, sociodramatic play has been supported by Vygotskian researchers, such as Elena Bodrova and Deborah Leong, and is recognized as an essential part of their Tools of the Mind curriculum that is based on a Vygotskian understanding of children's cognitive development.

In recent decades, sociodramatic play has been an important part of daily schedules in preschool and kindergarten in the United States. Many early childhood classrooms have dramatic play as an essential center for children to choose during free play time. However, since the standards movement toward academic outcomes has impacted early childhood education, many early childhood classrooms have reduced or removed free play time. As a result, dramatic play centers were one of the activities that quickly disappeared from kindergarten classrooms, and sociodramatic play was deleted from many kindergarten curricula. Early childhood educators today express concern about the lack of opportunity for children to engage in sociodramatic play. Based on current and continuing understanding of child development and children's approaches to learning, frequent calls are made for sociodramatic play to be reconsidered in contemporary early childhood education.

Characteristics

Sociodramatic play is known as a higher form of play demanding complex thinking skills, such as symbolic and abstract thinking. In order to engage in sociodramatic play successfully, children need to practice many skills. Smilansky presented six elements that can be used to evaluate well-developed sociodramatic play.

- The first element is taking on a make-believe role. A player takes on a make-believe role and

imitates the action and/or verbalization. For example, a child says, "I am a waiter" and pretends to place water glasses on a table.

- The second element is make-believe with regard to objects. A child pretends that one object is another item. For example, a child holds a pencil and pretends to cut a cake, using the pencil as a knife.
- The third element is make-believe with regard to actions and situations. A child pretends the actions of the role he or she is taking on. A child pretends to take care of a baby by rocking a doll and feeding it with a bottle.
- The fourth element is persistence. High-quality sociodramatic play can be sustained for longer periods of time. Children continue to play the same episode with some variation for a certain period of time that increases with the complexity of play themes and activities.
- The fifth element is interaction. Two or more children interact socially during the play episode, conversing about the play theme, and sometimes assigning roles.
- The sixth element is using language to communicate during the play. Children verbally communicate with each other during the play episode. Communication is a key to carrying out their play episode. If a child wants to pretend play about a restaurant and wants to invite other children, the child could say, "Welcome to our restaurant. What would you like to order?" and assume the role of waiter within the play, or directly ask, "Do you want to play restaurant?" and not assume the role.

High-quality sociodramatic play includes all six elements. It is notable that research suggests that children need at least 30 minutes to engage in high-quality sociodramatic play. Longer time allows children to explore their ideas and plan their play episode.

Developmental Benefits

The value of sociodramatic play can be found in all areas of development, including cognitive development, social-emotional development, and language and literacy development.

Sociodramatic play allows children to explore, experiment, and create their understandings of characters, events, and objects. For example, to pretend a restaurant theme, children collect their own experience and knowledge about what happens at the restaurant and create a mental picture or schema (organized thought) to act out what they know about restaurants. Children pretending to be a chef need to understand the role of a chef in the restaurant, select actions to imitate the chef, and learn to concentrate on the role. They also need to understand the role of other children and react appropriately to the context. They learn to control themselves and discipline their own actions in relation to the context. They learn flexibility in their approach to various situations that other children create because other children's experience with restaurants may be different from their own. With repeated play, successful sociodramatic play continues to expand and change with additional experiences and knowledge.

Cooperation and social interaction are essential in successful sociodramatic play. Children need to understand the roles they are playing as well as the roles of other people. They need to cooperate with each other and negotiate any problems that might happen during the play. Sociodramatic play provides a context for children to learn and practice their social skills. If they fail to cooperate or negotiate, they are not welcomed by other children and can be left out of the play. Children need to consider the perspectives of other players. For example, during restaurant play, players must negotiate the direction of the play episode. They need to negotiate who will be chefs, servers, and customers. The chef needs to maintain the role of chef. If the chef acts as a customer, players will address the problem and have to find a way to resolve the issue to continue their play, or the play will stop. Players can suggest that that is not what the chef does and the chef must accept others' suggestions.

Another benefit is the development of self-regulation skills. Lev Vygotsky, a Russian psychologist, placed a special emphasis on sociodramatic play as a way to achieve self-regulation—the ability to control one's impulses and adapt and behave

according to social norms. More recently, developmental psychologists Cynthia Elias and Laura Berk at the Illinois State University reported that sociodramatic play is advantageous for impulsive children to develop self-regulation skills and essential to later expectations of appropriate school behavior.

Sociodramatic play also contributes to the language and literacy development of children. Dramatic play and language and literacy learning share the same basic cognitive mechanism, symbolic representation. Language and literacy learning involve understanding abstract symbols representing other concrete objects and actions.

Dramatic play also requires children to understand the make-believe situation through use of symbolic thinking. Understanding that the word *apple* represents a kind of fruit shares the same underlying cognitive process as when a child pretends a block is a telephone. Both dramatic play and language and literacy learning are based on understanding symbolism. A body of research studies found that dramatic play facilitates children's emergent literacy and provides a natural context to develop children's awareness of concepts of print, oral language, and writing. When the dramatic play center includes literacy materials such as environmental print, labels, books, and writing materials, children experiment with these literacy materials naturally while they are playing. In restaurant play, for example, they might pretend to read a menu, write an order on a note pad, or print their names as part of their play, thus learning literacy in more enjoyable and developmentally appropriate ways. Language and interaction are two essential elements of sociodramatic play. Children improve their oral language skills and learn new vocabulary as they engage in pretend play. Adults' intentional support is important in learning language and literacy during play. The following section outlines the strategies Smilansky developed for adults to support children's sociodramatic play.

Sociodramatic Play Training

Whether and how adults need to be involved in children's play has been debated. However, recent

research has shown the benefits of adult involvement in play. According to Smilansky's play training, there are two basic types of sociodramatic play training: (1) inside intervention and (2) outside intervention. Inside intervention is an active coplayer role (when an adult takes on a role and participates in play with children). Adults demonstrate a model of high-quality sociodramatic play by exhibiting all six characteristics of sociodramatic play outlined by Smilansky. Inside intervention is a more direct way to teach children the tools for high-quality play. For example, in doctor play, an adult may take on the role of doctor with the children pretending to be patients. In the doctor role, adults act out what a doctor might do and say. Later, children can take on a doctor role, and they can begin by imitating what they learned from the teacher playing that role.

Outside intervention is applied when adults remain outside of the play episode and make comments or suggestions to children when the play seems to need some direction. For example, if children in a restaurant play seem to order the same food repeatedly (e.g., pizza), the adult might suggest that they order different kinds of foods, such as spaghetti or salad. This will encourage children to use different materials and different actions. When adults use outside interventions, it is important to address comments to the role that the child is playing instead of the child's real identity so that he or she can continue to be in a make-believe situation. Outside intervention is less intrusive to children's play. It is recommended to begin with outside intervention and assess for effectiveness before applying inside interventions.

Adults can also take on a variety of roles to support sociodramatic play, such as onlooker (being an appreciative audience), stage manager (helping set up the play), coplayer (role playing), or play leader (active role of role playing). All of these strategies are known to support and encourage children as they engage in sociodramatic play.

SOCIOMORAL DEVELOPMENT

Sociomoral development reflects children's social understanding of sociomoral events, which are events that focus on the prescriptive limits of interpersonal behavior, such as events involving the victimization of others or the following of social conventions. Research shows that children can distinguish between events that are straightforward social conventional and events that are straightforward moral. In early childhood, however, children have trouble coordinating events that involve multiple competing factors such as when conventions might compete with moral principles. This entry provides an overview of social development theory that drives research on sociomoral development in early childhood, and it reviews research findings documenting judgments and reasoning about sociomoral events, as well as the implications for this research in promoting sociomoral development in early childhood classrooms.

Overview

Children's judgments and reasoning about sociomoral events have been studied by Jean Piaget and Lawrence Kohlberg. Both have proposed

stagelike theories of development, in which preschoolers are described as being focused on avoiding punishment when making judgments and reasoning about sociomoral events. These theories assume that moral principles are acquired gradually with age, and that moral reasoning does not appear till much later in development. More recent research by Elliot Turiel and colleagues, however, documents more than 40 years of empirical findings showing that children from as early as 1 and 2 years of age are aware of moral rules concerning others' welfare and fairness as well as social conventional rules concerning traditions and conventions that are sanctioned by authorities. In addition, by 2 years of age, children use moral reasoning when asked about the acceptability of straightforward sociomoral events, such as hitting and stealing. Thus, children show concerns for the welfare of others from a very early age. Children construct their knowledge about sociomoral events and how to respond to them through reciprocal interactions with adults and peers, as well as by trying to resolve social conflicts and problems in everyday life.

Research

Research findings show that mothers and teachers apply rules and commands in ways that differentiate between moral and social conventional rules and situations. Children also experience social interactions in many different ways. They experience moral events as victims, victimizers, or bystanders, while they experience social conventional situations in the context of norms and rules, such as those that help a classroom run smoothly. By age 3½ children begin to distinguish between events that violate straightforward social conventions (e.g., talking out of turn) and events that violate moral principles (e.g., hitting a peer). Children, as do adults, consider that moral rules, unlike social conventional rules, are applicable in the absence of authority sanctioning and are generalizable to other contexts and cultures. In addition, by age 3, children can also distinguish between social and moral situations

and those that are personal (e.g., choice of clothing and friends).

While some sociomoral events are straightforward (i.e., either just morally relevant, or just related to social conventions, or just a matter of personal choice), most sociomoral events are multifaceted and require children to coordinate between multiple concerns to resolve them. For example, sharing blocks equally among friends is fair but might come at a cost to a personal preference of having more blocks. Five-year-olds begin to demonstrate the ability to coordinate between competing concerns. This may be partially explained by children's competence in theory of mind—the ability to understand that others have desires, knowledge, and beliefs that are different from one's own desires, knowledge, and beliefs. Theory of mind develops at around 4 to 5 years of age. At this age, children are more likely to understand that those who commit a moral transgression may have different beliefs, and children use that knowledge to assess whether a transgression is acceptable or not. Three-year-olds, on the other hand, judge moral transgressions to be unacceptable irrespective of what they know about the transgressor's beliefs or intentions. Theory of mind ability allows children to incorporate others' intentions, desires, and beliefs into their moral judgments and reasoning.

In addition to theory of mind abilities, children's affective experiences may influence how they remember, process, and understand moral transgressions. Emotions, therefore, play a role in how children evaluate moral transgressions. When responding to moral or conventional transgressions, studies show, teachers and parents use affect in different ways, focusing more on the emotional repercussions of moral transgressions such as harm inflicted on the victim, than when social conventional transgressions are committed. In early development, children view moral transgressions as emotionally negative while social conventional transgressions are viewed as emotionally neutral. Research has shown that children as young as 4 years use information about their own emotions and what others feel to infer whether sociomoral

events are morally relevant or not. Preschoolers, however, tend to attribute positive emotions to those who morally transgress although they recognize that victims of the transgression would feel bad. With age, typically developing children begin to expect transgressors would experience negative emotions (such as guilt, anger, and shame) after inflicting harm onto others.

Implications

The research findings have multiple implications for applications in the home and in the classroom. Early sociomoral development occurs in trusting and fair environments that encourage children to apply their concepts of fairness, human welfare, and rights to everyday life issues that come up in both interpersonal relationships and societal practices. Caregivers and teachers who aid children in their coordination of multifaceted sociomoral events by highlighting components that are moral and those that are not and encouraging children to take multiple perspectives help children develop an ability to navigate sociomoral events. In addition, research on moral education has shown the benefits of environments that encourage moral discourse, as well as reflections on the motivation for a transgression, the feelings of those involved, and the consequences of actions on others. Reciprocal social interactions are essential opportunities for children to experience sociomoral events and resolve conflicts that may arise from them. Thus, caregivers, teachers, and schools foster children's sociomoral development by providing safe and positive environments for children to engage in social interactions with both adults and peers.

SPATIAL DEVELOPMENT

Many words have been used in the early childhood literature to describe spatial development, including such terms as *spatial cognition*, *spatial literacy*, *spatial concepts*, and *spatial intelligence*. Spatial development is often referred to and characterized in early childhood literature as the ability to problem solve operations. These operations are mental rotation, a spatial skill that involves thinking about objects in different spatially oriented ways (e.g., seeing wheels on gears go in different directions); perspective change (the visualization of objects from different perspectives such as producing a mental image of objects from two points of view), and coordinated use of space (coordinating how space is utilized in relation to another space such as organizing blocks in a given space); representation (depicting by image an object or place on a map); and reasoning (the ability to understand and explain how items are arranged in space and in relation to one another). These definitions have been modified in the literature and assessed in various ways to promote an understanding of spatial development.

Spatial development has been identified as a key component in STEM disciplines (science, technology, engineering, and math) and also the arts. High-quality studies conducted over the last

century indicate that spatial thinking is critical to STEM success. Although many of these studies were conducted with high school students, recent reports have shown that early attention to developing spatial thinking could promote interest in STEM fields. This entry is devoted to current findings from the research and curriculum to promote spatial development.

Research

It is thought that some biological processes could account for the reason boys score higher on spatial development assessments than girls. Researchers have been inconsistent in what age the differences in gender exist. The question has been raised whether experiences playing with certain toys could account for boys scoring higher than girls. Some of the major research results specific to spatial development have been the following:

- Boys play more frequently with blocks, manipulatives, puzzles, balls, and transportation toys than girls do.
- Boys tend to score better than girls on spatial tests.
- With practice in spatially challenging environments and curriculum, girls can make gains in spatial development.

Methods for Increasing Spatial Development

Various methods for increasing spatial development in young children have been recognized: gestures, visualization, diagrams, grids, block playing, mapping, computer games, puzzles, children's stories, appropriate vocabulary, and practice. Using gestures is one way of helping children increase spatial understandings. This method involves having children talk and gesture at the same time so that information can be captured by children who may not be able to verbalize without gestures. Visualization provides learners with information to promote problem solving in the spatial field. For example, helping children

visualize what happens when a ball is rolled down two ramps of different sizes encourages the child to think about spatial relations.

Diagrams and grids also help the child develop spatial orientation. Block playing with different types of blocks promotes spatial and geometric vocabulary development and problem solving. Mapping skills help children orient themselves in space. Mapping is facilitated by the learning of routes in the classroom, the school, and the neighborhood that are basic to the understanding of spatial skills. Teaching children landmarks to follow is an important part of mapping.

Computer games can assist the child with manipulations in different spatial orientations. Computer skills can aid metacognition, visualization, and conceptual thinking. Puzzles help with mental transformations, matching shapes, and problem solving. Puzzle play should include regular puzzles as well as tangrams and other geometric shaped puzzles. A tangram is puzzle that has seven pieces that can be fitted together to make a square.

Children's stories can be a source of drama and an understanding of spatial words as well as an impetus for block construction. Vocabulary enrichment can utilize "spatial words" such as *on/off*; *on top of*, *over*, *under*; *in*, *out*, *into*, *out of*; *top*, *bottom*; *above/below*; *in front of/in back of*; *beside*, *by*, *next*; *between*. Children also can learn "direction words" such as *up*, *down*; *forward*, *backward*, *around*, *through*; *to*, *from*; *toward*, *away from*; *sideways*, *across*. "Relative distance words" can be used to develop concepts such as near, far, close to, and far from. Practice in thinking geometrically and spatially should be an important part of the school day utilizing all curriculum areas in early childhood.

Curriculum Models That Emphasize Spatial Development

Friedrich Froebel, the father of kindergarten, established a kindergarten that provided a spatial challenge. Froebel, a trained mathematician, architect, and mineralogist, utilized *gifts* (objects that represent symbolic ideas and can be used for

construction, design, and math and science). In addition, he used handiwork activities, called *occupations*, that can be used in conjunction with the *gifts* such as sewing, perforating, braiding, paper folding, paper cutting, and clay modeling. The geometric abstractions of the work of students in Froebel's schools are seen in the work of architect Frank Lloyd Wright, the Bauhaus designers, and the geodesic dome of Buckminster Fuller. Maria Montessori also promoted spatial development with a large assortment of geometric blocks and geometric shapes. The Reggio Emilia schools of Italy have emphasized the keen study of art with perspective in their long-term projects. The Asian countries have had a history of paper folding and tangram puzzle use to promote geometric concepts. Contemporary researchers Doug Clements and Julie Sarama have helped develop a preschool curriculum that has been shown to improve mathematics and spatial development in young children.

SPECIAL NEEDS

Special needs is a term that is used generally to describe anyone with a physical, cognitive, or mental disability, challenge, or delay. Depending on the audience or the discipline, the term can have varied meanings and applications. When referencing issues that are completely medical in nature, more specific phrasing will be used, such as the term *special medical needs*. This category is typically used when referencing diagnoses such as hemophilia and epilepsy.

Within the foster care/adoption system, the term *special needs* has a much broader definition. With regard to adoption, it is a legal term applying to those eligible for federal financial assistance. This can include those individuals with disabilities but also includes other demographic factors such as age, ethnicity, and membership in a sibling group.

Although there are these additional uses, the term is typically linked to education and is often considered an abbreviation for special education needs. It is frequently used in reference to children and encompasses everything from blindness to cerebral palsy to dyslexia. The term is used when the actual diagnosis is known, such as with a child with an autism spectrum disorder, and in cases in which there is no definitive diagnosis. The term does not denote severity of involvement, but rather references the need for additional supports of some kind in order to participate in education broadly. In order to fully understand the concept, it is important to understand how it is and is not used, the legal ramifications and applications of the term, and the innovative practices that impact those for whom this term applies.

This entry discusses the language used when discussing children with special needs and laws regarding children with special needs, including legislation dealing with the education of preschool children. It then discusses technology that can be used with young children with special needs and advances in research on children with special needs, their development, and educational interventions.

SPECIAL EDUCATION

See Early Childhood Special Education

Other Terminology and Person First Language

The phrase “children with special needs” is currently the preferred phrasing by educators, advocates, and parents, rather than “children with exceptionalities” or “children with disabilities,” although these phrases remain common in earlier publications and legal documents. Consistent in this phrasing is “children with.” This approach to terminology is referred to as *person first language*. The premise behind this concept is that the ordering of the words suggests importance. Thus if the terminology for the diagnosis is placed before the word *child*, the focus is on said diagnosis rather than on the child. When the word *child* or *individual* is placed before the diagnosis, it recognizes that the child is a child first and also has a disability or special need. This is typically generalized to specific diagnoses as well, so the preferred phrasing is “child with Down syndrome” rather than the Down’s child or the special needs child.

The Laws

The term *special needs* is inextricably linked to special education as it evolved from the concept that there were children who had educational needs that were different from their typical peers due to biological and/or environmental factors. As such, it is important to understand the evolution of the laws that serve to regulate how these children and their families are identified and served.

Although the existence of adults and children who are differently abled has been documented as early as the existence of the written word, the rights of these individuals are relatively new in the United States and continue to evolve globally. This is particularly true with regard to educational rights. There are millions of children with special needs around the world, but their access to education and resulting acceptance into society is inconsistent at best. This struggle is amplified in countries with high levels of poverty in which, according to the United Nations, 98% of children with disabili-

ties do not attend school in any form. In 2006, the United Nations held the Convention on the Rights of Persons with Disabilities (CRPD) and produced an international document outlining a structure for the human rights of individuals with disabilities. The CRPD emphasized education as a priority for children with special needs including calls for inclusion, education in typical settings, and with typical peers.

In the United States, the first special education law passed by Congress in 1975 was entitled the Education for All Handicapped Children Act (EHA). EHA or Pub. L. 94-142 was groundbreaking legislation and required a free and appropriate public education (FAPE) for all students with disabilities. This law was later renamed the Individuals with Disabilities Education Act (IDEA).

In 1986 Congress passed Pub. L. 99-457, the Education of the Handicapped Act Amendments. This seminal piece of legislation expanded the provisions of Pub. L. 94-142 to include services for infants, toddlers, and preschool children with special needs and their families. This was a dramatic shift and recognized the importance of early intervention. These laws expand the concept of FAPE and require states to make available appropriate and free public education to children ages 3 through 5 with special needs. The law also created an incentive system in which states that offer interdisciplinary educational services to infants and toddlers with special needs and their families receive federal financial grants. This law is consistent with and advanced the concept of family-centered practices in early intervention, and it recognized the unique nature of early intervention.

Additional language that is included in these provisions involves related services. Related services are a part of special education that includes services from professionals from a wide range of disciplines that are often outside of what is typically considered education. Although these services are available to children of all ages, they are particularly relevant for young children as we know that delays or issues in one developmental domain can

impact other areas of development. These professionals commonly include but are not limited to occupational therapists (OTs), physical therapists (PTs), speech-language pathologists (SLPs), school psychologists, and social workers. Depending on the needs of the child, augmentative communication specialists and board certified behavior specialists may also be included.

The goal is for these individuals to work together to address the educational needs of each child. There are a variety of models for how these services are delivered and how these professionals work together. In a discipline-specific service delivery model, one professional provides services to the child within his or her domain of expertise. For instance, a child who is dysfluent might work only with a speech therapist. A multidisciplinary approach involves a group of professionals. Although there are many professionals involved in this approach there is often little or no communication among the professionals, each implementing his or her intervention separately from the others.

Interdisciplinary teams also have more than one profession represented and in these cases there is a significant amount of communication between the professionals. They share intervention plans and often work in tandem with the child. The most collaborative teams utilize a transdisciplinary model. These teams plan together and often engage in role release. For example, the speech therapist will train the occupational therapist so that he or she can implement speech and language techniques while engaging in OT activities. Although the individual therapists remain the experts in their particular domain, they infuse this expertise into other aspects of the child's programming and assume partial responsibility for implementing the interventions from the other domains as well.

An individualized education program (IEP) is a written plan used to document an individual student's current level of development and his or her learning goals. The IEP is required by law for children ages 3 and up with special needs and outlines the specific accommodations, modifications, and

related services that a student might need to attend school and to receive reasonable benefit from that educational experience. For very young children, those under 3, an individualized family service plan (IFSP) is created to record and guide the early intervention process. This document is written to reflect individual concerns, priorities, and resources for infants and toddlers with special needs and their families.

Technology

The general field of education is growing and changing at a rapid pace. The emphasis on technology has been at the forefront of these discussions, and technology has certainly had an impact on children with special needs. Assistive technology refers to any device or application that allows an individual to perform a task or engage in an activity that he or she would otherwise be unable to do or would have had a great deal of difficulty accomplishing. The underlying concept is that the effective use of these devices yields greater independence for those utilizing them.

Assistive technology devices or apparatuses can be used to address challenges in any developmental domain including, but not limited to, wheelchairs or talk-to-text devices for physical impairments and augmentative communication systems for communication disorders. Although the term includes the word *technology*, the applications can be either high or low tech. Computer-generated voice-output devices are considered high tech while picture exchange systems are considered low tech. Both are used with young children who are unable to communicate effectively through verbal means.

Research and Innovation

Innovation approaches and research foci regarding children with special needs have changed dramatically in recent years. Research in the effectiveness of educational interventions for children with special needs has produced very promising results in improving the lives

and the developmental trajectories of these individuals; however, advances in medicine and psychology are poised to drastically change how we view these children, particularly those with special needs of known or identified genetic etiology.

Etiology refers to the cause of something, in this case the reason for the delay or developmental concern. Etiologically specific information regarding disability-specific profiles and developmental trajectories has exploded during the past decade. Advances in the fields of psychology, education, and medicine have been extensive but to date have worked within silos, thus limiting collaboration and the sharing of information. Translational research, or the use of information from pure science in clinical settings, is beginning to bridge this gap.

Phenotypic profiles for children with known etiology can often provide clinicians and educators with a framework from which to begin interventions or therapies. Although each individual by definition is unique, for children with special needs of known etiology, the interventionist does not need to start from an uninformed position. It is important to note that although the emphasis is often on education, the essential information on the conditions of these children resides outside the field of education. It is important to open a dialogue about the issues regarding effective assessment practices and current concerns and then to share available information.

In parallel with the advances in etiologic and phenotypic profiles have been advances in understanding the neurobiology of specific genetic disorders such as Down syndrome and fragile X syndrome. Once the chemical pathways in the brain had been identified, biochemists and pharmaceutical researchers began creating medications or targeted treatments designed to restore the compromised neurological pathways and structures. The use of these targeted treatments is very new but could quite possibly change the way in which individuals with special needs receive treatment.

SPEECH DEVELOPMENT

Speech development is the process that begins at birth and continues through adolescence when children learn to use sounds and words to communicate meaning and develop the prerequisite skills to early literacy. Children reach milestones in speech development in predictable stages typically by 6 years of age with variations in the rate they acquire speech sounds and speak their first words. Normal human speech is produced with air pressure from the lungs that causes phonation within the larynx, or “voice box,” that is subsequently modified within the vocal tract through the coordination of muscle action of the tongue, jaw, and lips to produce the different vowels and consonants that make up language.

Phases and Sequence of Speech Sound Acquisition

Ken Bleile identified four phases of speech sound acquisition highlighting the prerequisites for speech sound production, transitions from sounds to words to speech with mastery of literacy.

Phase 1—Laying the Foundations for Speech

This first phase occurs from birth to 1 year and it is during this phase that the vocal tract or oral motor mechanism makes significant changes. The structure of an infant’s vocal tract is initially geared for survival; its sole function is the coordination of breathing, sucking, and swallowing in order to take in nourishment. The articulatory movements of the vocal tract components mature in a typical sequence beginning with the jaw and lip movements, which become almost adultlike prior to a child’s second birthday. On the other hand, the tongue’s adaptability and its highly variable articulatory movements in position/contact with the palate can make significant transformations and refinement with changes occurring in children up until the age of 11 years. Infant perception is another important foundation in speech acquisition, and it is during this phase that infants sharpen their ability to recognize

and respond to auditory stimuli and discriminate between voices, speech sounds, and environmental noises and sounds.

Phase 2—Transitioning From Words to Speech

The second phase occurs from 1 to 2 years of age, when children are typically producing their first 50 words. Pronunciations are limited in complexity with consonants produced at the front of the mouth (e.g., /p, b, d, t, m, n/) predominating. First words also follow a sequence of simple to complex consonant (C) and vowel (V) combinations, beginning with consonant–vowel (CV) patterns as in “moo,” vowel–consonant (VC) patterns as in “up,” CVC words as in “bat,” and CVCV patterns as in “bunny.”

Phase 3—Growth of the Inventory

From 2 to 5 years of age, children are continuing to build their speech sound inventory. Intelligibility, the ability to be understood, becomes an important consideration especially because it can be affected by multiple linguistic factors such as articulation of phonemes (speech sounds), phonological processes, and prosody (aspects of sound production to include stress, intonation, and rhythm).

With typical development, the acquisition of speech sounds follows a predictable pattern from easiest to most difficult. The first set of speech sounds considered to be the easiest to produce are typically acquired between the ages of 1 and 3 and they include m, p, b, d, n, w, h, and y. The middle group, acquired between the ages of 3 and 6½, includes the sounds t, k, g, f, v, ch, j, and ng. The final and “later” set of sounds to be acquired are sh, s, voiceless th (as in “thumb”) and voiced th (as in “them”), r, z, l, and zh. Children vary in their development of speech and language skills with the most intensive growth occurring within the first 3 years of life. There is a wide range of what is considered within typical limits when children are learning to use different sounds, speak their first words, and build their vocabulary repertoire. The normal progression of speech milestones is explained in the following sections.

Birth to 3 Months. The first signs of communication are the cries of infants to express discomfort. They soon learn to vary their cries in order to be held, fed, or comforted as well as to make pleasure or cooing sounds when they are content.

By 6 Months. Children will imitate environmental noises or produce vowel sounds. They will babble in vocal play when happy or excited, will experiment with the sounds they hear, and will begin producing early speech consonants involving closed-lip postures such as /m, p, b/.

By 9 Months. Between 6 and 9 months, children begin to babble reduplicated syllables (e.g., baba) and use long and short patterns in vocal play. They will shout to gain attention, use a gesture for bye-bye, and gesture with lifted arms with or without a vocalization to request to be picked up by a parent. Consonant-vowel patterns with /p, b, m/ consonants are produced in their babbling.

By 12 Months. As children approach their first birthday, they typically have a vocabulary of approximately three to four words that they use consistently. These words are typically names for a parent or caregiver (e.g., Mama, Dada) or words to request (e.g., baba for “bottle”), and so on. They gain attention with sounds (other than fussing), and combine sounds in vocal play with variegated babbling (e.g., abaduh abee) or imitate the different speech sounds heard in their environment.

By 18 Months. At this age, children’s vocabulary has approximately 6 to 20 words and they are adding words on a regular basis. The child is using a minimum of four different consonants such as /b, n, d, g, w, or h/. The child is responding to Yes/No questions with gestures and words and has learned to say “no” to protest. The expected level of intelligibility (ability to be understood when speaking) is approximately 25%.

By 24 Months. The vocabulary of a 2-year-old will consist of 50 to 100 words including nouns, action words, modifiers, and pronouns. This quantity of words is necessary for the child to

start combining words into two-word phrases. Two-year-olds will form new words easily and continue to add words to their vocabulary. They will chatter with adultlike rhythm and begin to ask simple “Wh-” questions. The expected level of intelligibility is 50%.

By 30 Months. Children’s repertoire at 30 months will be approximately 350 words. Many vowel sounds are used within their words and the vocabulary will include words with two or more syllables. Previously acquired vocabulary words will have the addition of word endings (e.g., -ing, -ed, and plural s). Intelligibility of speech sounds is good with familiar people and continues to improve as the child is consistently producing consonants in the initial position of words. The child would have mastered the early speech sounds and begins producing some of the middle (age of acquisition) sounds /k, g, f, t/.

3 to 4 Years. Young preschoolers will use words for everything. With two- or three-word phrases, they will carry on simple conversations, describe what they are doing, and request items using pronouns. They may use 4+-word sentences, answer “Wh-” questions, or talk about daily activities. Speaking should be easy and without repetition. At the age of 3, children should be approximately 75% intelligible and at least 90% by the time they turn 4.

4 to 5 Years. Older preschoolers will be able to narrate their own stories with great detail. All vowel sounds, to include diphthongs (e.g., oy as in “boy” or ai as in “paid”), should be produced by the age of 4. The child can produce his or her early and middle-level speech sounds but still needs to work on /l, s, r, v, z, ch, sh, th/.

Phonological processes are the systematic and predictable patterns that children use to simplify adult speech as they are learning to talk. A few of the most common phonological processes are fronting (e.g., child says “tow” for “cow”) sounds produced with the tongue in contact with the front of the palate rather than the back of the palate; syllable reduction (e.g., “nana” for “banana”) when the child eliminates a weaker syllable; and

cluster reduction (e.g., “boo” for “blue”) when the child eliminates the later developing consonant *l* and produces the sound that is the easiest to say (i.e., /b/).

Phase 4—Mastery of Speech and Literacy

This final phase covers children from the age of 5 years on, typically when they are attending school. At this age, children are still mastering the later set of speech sounds sh, s, th, r, z, l, learning to use consonant blends (e.g., bl-, st-) and consonant clusters (e.g., str-), and developing the literacy skills for reading and spelling.

Phonological awareness is the ability to manipulate the sound structures of words in spoken language and is essential for the development of reading and spelling. It includes rhyme knowledge (i.e., understanding the essence of a syllable and how rhyme is created); blending/segmentation (i.e., ability to combine sound elements into words or separate words into syllables or phonemes); and manipulation of phonemes, clusters, and syllables to create new words.

Speech Sound Disorders

There is a wide range of what is considered typical for the mastery of specific speech sounds. However, when a child’s speech errors do not resolve themselves by a certain age, or the child is still having difficulties with being understood by familiar adults or is exhibiting frustration behaviors because the child is unsuccessful with his or her attempts to communicate wants and needs, a referral should be made for a speech assessment to determine if a speech disorder exists. Speech-language pathologists, or speech therapists, are the trained professionals who assess, diagnose, treat, and help prevent disorders that are related to speech, language, voice, fluency, and swallowing.

There are numerous causes for speech sound disorders both developmental and because of underlying medical diagnoses such as Down syndrome, hearing impairments, genetic abnormalities, and neuromotor impairments. The related difficulties with speech sound acquisition and their impact

on speech development can vary significantly as highlighted in the following descriptions.

Articulation Disorder

Articulation involves the adjustments and movement of oral-motor structures and coordination of the related musculature to produce speech sounds. The variations in sound production are achieved by altering the *place* (i.e., positions of the speech organs to create different speech sounds), *manner* (i.e., how the speech organs make contact to produce the different speech sounds), or *voicing* (i.e., turning the vibration of the vocal cords on or off) of the structures within the oral-motor mechanism. As young children are learning and practicing new speech sounds, they may make individual sound errors. The most common type of speech sound error is a *substitution* (the child replaces a target sound with a sound that is easier to produce, for example, when they say “pat” for “fat”). Other common speech sound errors include *omissions* (eliminating a target sound in a word, such as saying “ot” for “pot”) or *distortions* (when a child uses a nontypical sound for a typically developing sound, such as a lateralized /s/, i.e., Daffy Duck speech).

Oral-Motor Disorders or Dysfunction

Variations or weaknesses with the lips, tongue, palate, or nasopharynx may cause difficulties with speech production. These variations can be present from birth (e.g., cleft lip and palate) or acquired (e.g., trauma to the tongue, enlarged adenoids). Cleft lip and palate, the most common congenital orofacial anomaly, are birth defects that occur when a baby’s lip or mouth does not form properly during pregnancy. Surgical repairs will usually occur within the first year of life and may include prosthetic management.

Other orofacial anomalies that impact sound production include velopharyngeal insufficiency (i.e., weak or insufficient contact between the velum and pharynx), which impacts the control of airflow and often leads to hypernasal vocal quality or diminished intraoral breath pressure. Enlarged adenoids can cause an obstruction of

the nasopharynx and result in hyponasal/denasal speech (i.e., similar to someone's voice when they have a cold).

Speech Disorders Due to Genetic Factors

Genetic disorders such as Down syndrome and fragile X syndrome often have several features that can contribute to difficulties with speech production. For example, cognitive impairment, a common feature in both Down syndrome and fragile X syndrome, can impact a child's ability to learn speech sounds. Related hypotonia (i.e., low muscle tone) impacts both gross motor and fine motor skills to include the oral-motor structures. Another common feature of children with Down syndrome is *relative macroglossia*. The mouth is smaller than average, which makes an average-size tongue seem larger than normal so movement and function are impacted.

Hearing Impairments

Hearing loss is also a major cause of speech difficulties because the hearing impairment limits the auditory input for children to learn different speech sounds. A hearing loss can be congenital or acquired due to frequent and unresolved ear infections such as conductive hearing loss.

Neuromotor Disorders

Another group of children with organically based speech disorders are those with neuromotor disorders such as *childhood apraxia of speech* and *dysarthria*. Childhood apraxia of speech, also called *developmental apraxia of speech* and *developmental verbal apraxia*, is characterized as an impairment of motor speech programming with the presence of normal reflexes and tone. Dysarthrias, on the other hand, are characterized by a paralysis, weakness, or lack of coordination or precision in the speech musculature which results in slow, weak, or uncoordinated movements during speech production.

Stuttering

Stuttering affects the fluency of speech and is characterized by disruptions in the production of speech

sounds or words. These disruptions can include repetitions of single sounds, part-word or whole-word repetitions, blocked sounds (i.e., mouth is formed to say the sound, but the sound is delayed or not produced), interjections (e.g., adding fillers such as "uh" or "like"), or prolongations (e.g., uuuummmm). A child who stutters will have a higher risk of having speech sound disorders due to many factors: (a) Children who stutter will often avoid the sounds or words that they tend to get "stuck on," (b) stuttering is more common with certain disorders such as hearing impairment and Down syndrome, or (c) the child may not have the skills to simultaneously handle the multiple aspects of language and speech.

Voice Disorders

Voice disorders in children are typically due to phonation problems that are often attributed to voice-abusive behaviors (e.g., yelling, screaming) or issues with reflux. Symptoms such as hoarseness, breathiness, or harshness may negatively affect speech sound production and overall intelligibility.

SPEECH DEVELOPMENT, ISSUES IN

Speech development is a process that begins early in childhood. For many children, this process begins early in infancy and unfolds at an appropriate rate. The result, for these typically developing children, is articulate speech by approximately 6 years of age. However, there is a group of children for whom speech does not develop typically. There are a wide range of etiologies for this atypical development. This entry provides information about typical speech development as well as several possible explanations for difficulty acquiring articulate speech.

Overview

Speech development begins very early for most typically developing children. Vegetative and physiological vocalizations (e.g., grunting, crying, cooing) quickly become a means of communication. Early in infancy, babies begin to play with their vocalizations by stretching out the length, pitch, and frequency of their productions. Between 4 and 12 months of age, infants begin to explore their articulators—the anatomical parts used for speech production, such as the lips, tongue, jaw, and velum. Around their first birthday, most children are producing a simple first word that is often comprised of early developing speech sounds (e.g., /p, b, t, d, m, n, w/ and vowels). Language and speech develop reciprocally at this time. As children's vocabularies expand, so do their opportunities to produce new

and more complex phoneme combinations. More difficult phonemes (e.g., /s, z, k, g, l, r/, "ch, sh, th") develop between the ages of 2 and, arguably, 7. For the majority of children, their speech sound system is completely developed with intelligible speech around the age of 5.

For some children, however, speech development occurs at a slower, or atypical, pace. These children have speech sound disorders. *Speech sound disorder* (SSD) is an umbrella term used to refer to difficulty with the production of phonemes. Over the years, multiple terms have been used to refer to this disorder: *speech delay*, *articulation disorder*, *phonological disorder*, and *speech impairment*, for example. All are still acceptable, but the field of speech language pathology uses speech sound disorder to encompass them all.

Broadly, there are two primary etiologies of SSD: (1) organic and (2) functional. Organic speech sound disorders have a known cause, which may range from structural abnormalities (e.g., cleft palate) to neurological/neuromuscular disorders (e.g., cerebral palsy). Functional disorders, on the other hand, do not have a known cause. The speech sound disorders exist in the absence of any overt structural or neurological issues; the child is otherwise typically developing in many cases. Although many believe and continue to purport that chronic otitis media in early development creates a risk for an SSD, substantial research has been provided to the contrary.

Theory

Two competing theories regarding the underlying cause of functional SSDs are cognitive-linguistic and sensory-motor. Cognitive-linguistic theories suggest that SSDs arise from deficits in the language system. That is, the phonological system is flawed in a way that creates difficulty in producing accurate phonemes. One intriguing aspect of these theories considers that perhaps children with SSD do not fully acquire phonological representations—the building blocks for learning spoken and written language. Sensory-motor based theories suggest that individuals with SSD struggle with phoneme production due

to underlying motoric deficits. That is, the language system is intact, but the motoric system lacks the planning, coordination, and/or strength to accurately produce target sounds.

Research

Current research in this area has several primary foci. First, outcomes related to academic, social, and linguistic performance are of great interest. Although many children with SSDs remediate their errors after a course of treatment, some children persist. For children who persist with speech errors after interventions, gaining adequate literacy skills is a struggle. Difficulty with literacy leads to overall academic difficulties and in some cases, social struggles and, later, vocational struggles. Thus, it is prudent to identify these children early and provide services.

A second focus of research is risk factors. Though there are many risk factors associated with SSDs, research has reported that it is often the accumulation of risk factors that increases a child's probability of having an SSD. Additionally, many young children with functional speech delays eventually achieve age-appropriate speech production. As such, the estimated prevalence of 6-year-olds with an SSD is 3.8%; boys are at greater risk than are girls, with current ratio estimates ranging from 2:1 to 3:1. What remains unclear is what factors influence the development of normal speech for those children who do remediate by age 6 in comparison with those children who are part of the 3.8%.

Finally, a third focus of research examines effective treatment methods for children with SSDs. The aforementioned theories regarding the cause of functional speech sound disorders also dichotomize common therapy approaches (i.e., cognitive-linguistic and sensory-motor). Therapy implementing a cognitive-linguistic approach would focus on teaching the child the connection of the sound to the language; possibly identifying the letter to which it most commonly corresponds or by contrasting it with the errored sound. Therapy implementing a sensory-motor approach would focus on

teaching the child how to accurately move the articulators of speech in order to achieve the most appropriate sound. However, surveys of speech language pathologists indicate that, most commonly, an eclectic approach of both is implemented during treatment.

Importantly, because of the possible academic, cognitive, and linguistic outcomes for children with speech sound disorders, it is crucial to identify and intervene early. Parents, caregivers, and teachers are strongly advised to seek the advice of a speech-language pathologist if they are concerned about the status of a particular child.

SPIRITUAL DEVELOPMENT

Interest in the spiritual development of young children is a relatively new phenomenon in the field of human development. Awareness of children's spirituality and spiritual development has increased in recent years partly because of the perception that spirituality is an integral part of human existence and cannot be ignored in educational settings.

This awareness has motivated additional research resulting in discussion and opportunities to consider the spiritual development of young children as an essential component in human development. This entry (a) offers an overview of spiritual development in young children, (b) explores the characteristic dimensions of spiritual development, (c) summarizes the work of theorists who have studied children's spiritual development, and (d) provides implications for teachers to recognize the spiritual development of a young child as a domain in human development.

Overview

Spirituality can be defined in many ways: Some definitions focus on self-awareness as it affects relationships and moral understanding. Others address the importance of nature and outdoor play for young children. A child's spiritual development can be recognized as relational, that is, encompassing compassion, truthfulness, loving-kindness, simple living, and peaceful resolution of conflicts.

The spiritual development of a young child is holistic, involving the body and spirit, thoughts and emotions. The essence of spiritual development is the education of the whole child. The spiritual development of a young child, which involves an awareness of nature and a sense of belonging, is nurtured with security and trust, firsthand experience with nature, and loving relationships with family and caregivers.

Supporting the spiritual development of young children is not about teaching religion. The spiritual development of a young child is characterized by inner experiences, not the observance of customs that may be tied to a particular faith tradition. Promoting dispositions associated with the spiritual development of a young child supports social and emotional lessons that guide social justice, caring for others, community with others, and positive emotional well-being. Like all intentional teaching activities and practices, those that support spiritual development are established in authentic, developmentally and culturally appropriate

learning opportunities and play that occur naturally during a child's day.

Dimensions of Spiritual Development

The following characteristics accompany the spiritual development of young children: simplicity, wonder, openness to new experiences, and trust. As a child's spiritual development occurs, concern for others grows. Spirituality derives from living, exploring, and belonging and from building close relationships created in comfortable environments with loving caregivers who provide a consistent, secure environment and routines for optimal development.

According to David Hay and Rebecca Nye, children's spiritual development comprises three dimensions: (1) awareness-sensing, (2) mystery-sensing, and (3) value-sensing. Awareness-sensing, which involves a child's focus on the here and now, includes tuning in to new sensory experiences, often aesthetic, and living experiences in moments of solitude and concentration. Spiritual experiences of children can also be considered mystery-sensing, characterized by wonder. Childhood is a time of wonder as young children look at the world and capture it through fresh eyes and ears. Wonder includes experiences that are joyful, awe inspiring, and connected to nature. This type of sensing refers to the wonder, fascination, and questioning characteristic of young children as they interact with their universe. The third dimension of children's spirituality is value-sensing, which involves emotions and the way children express their values in the intensity of everyday experiences.

Theorists

A child's spiritual development begins at infancy and continues throughout adolescence. In the 1980s, James Fowler introduced spiritual development, comprising eight stages, starting with infancy and ending with a universal faith, much like Lawrence Kohlberg's moral development stages. According to Fowler, as young children

grow in their ability to form relationships, to develop empathy and reciprocity, they grow in spirituality. This characterization of spiritual development builds on Erik Erikson's theory of trust versus mistrust and Margaret Mahler's theory of attachment–separation in early childhood. These two theorists concluded that spiritual development requires nurturing attention from caregivers so that they develop attachment to their caregivers, both at home and at school. Basic trust is thus essential. Jean Piaget also contributed to the formation of spiritual development by encouraging parents and teachers to offer materials, activities, and open-ended questions that support the development of a child's thinking.

Implications for Teachers

The spirituality of young children can be nurtured in the classroom in quiet areas set up to allow a child to observe a pet or a plant. Children need an environment where they can look outside to view nature, reflect, and breathe. Other ways to nurture the spiritual development of a young child include planting a year-round garden, adopting a tree, observing the change of seasons, and taking care of the Earth. In addition to supporting a child's spiritual development, these measures also transport the child closer to nature.

One of the best ways to nurture spirituality in a classroom is by creating a sense of community and working together as a family of learners. Posting pictures illustrating a classroom community helps children realize they are part of that family of learners. For example, painting murals together, creating a puppet play together, and singing together during circle time assure children that their ideas are respected and that they need one another. Honoring all cultures by celebrating holidays and traditions in developmentally appropriate and sensitive ways is another approach to bring spirituality into the classroom. Doing so gives each child a feeling that he or she is special.

Early childhood is a time when young children seek opportunities to make sense of the world around them. The spiritual development of young children celebrates resilience; increases

self-confidence; and gives them courage, humility, and self-acceptance. Just as early childhood educators support other domains of a young child's development, they should also enthusiastically promote children's spiritual development.

STAGE THEORIES

Stage theories characterize human development as a series of distinct phases during which skills and abilities appear abruptly at the beginning of a stage and are maintained steadily until the start of the next stage. Children in a particular stage of development are seen as behaving and thinking qualitatively differently from the way they function in other stages, primarily because of major attainments or reorganizations that have taken place. The elements that characterize a particular stage are presumed to permeate many aspects of functioning within that stage. In many stage theories, stages are tied to specific ages, advances are built on the foundations laid within earlier stages, and there is a steady and universal progression toward higher levels of functioning. Implied in many stage theories is the idea that maturation is responsible, at least in part, for development and that regression back to earlier modes of functioning is not possible.

Stage theorists see the process of development as *discontinuous*, with major advances occurring between the end of one stage and the start of the next, and acquisitions remaining relatively flat within a stage. Stage theories stand in contrast to *continuous* theories, which characterize development as taking place through small, gradual, quantitative advances that, in many theories, proceed in a linear and incremental fashion.

Several stage theories have been prominent in the history of developmental psychology, including Jean Piaget's theory of intellectual development, Lawrence Kohlberg's theory of moral development, and Erik Erikson's theory of identity development. Contemporary theories, such as information processing theory and social learning theory, focus less on stages and more on continuous features of cognitive and socioemotional development. Other newer theoretical approaches such as systems theories are also nonstagelike; rather, they emphasize convergent factors at the biological, cognitive, social, and cultural/environmental levels that coalesce to result in advances in development.

Piaget's Theory of Intellectual Development

Piaget (1896–1980) hypothesized that cognitive development is organized into four major stages that reflect qualitatively different central operating principles in children's thinking within each period: the sensorimotor stage (ages birth to 2 years), the preoperational stage (ages 2 to 5 years), the concrete operational stage (ages 5 to 9 years), and the formal operational stage (ages 9 years and onward). Piaget viewed developmental advances as arising from basic adaptive and organizational processes within the organism that operate in conjunction with opportunities for the child to engage actively with the environment. The result is the modification, and at the time a new stage begins, the reorganization of the mental structures, or schemas, that influence the child's thinking capacities.

The two principal stages relevant to the period of early childhood are the sensorimotor and preoperational periods. In the *sensorimotor stage*, infants build a collection of internal representations based

on their physical actions within the environment. Babies look, touch, and eventually crawl and walk, and in these actions, come to construct their understanding of the world around them. The primary basis for thought is action. Within the sensorimotor stage, the infant's actions become increasingly directed toward solving problems, and a representation of the world as separate from the self is constructed. An important attainment during this stage is the *object concept*, the realization that objects in the world continue to exist, even if they cannot be seen at a given moment.

The main acquisition of the *preoperational stage* is the child's ability to engage in symbolic thinking (i.e., the semiotic function), a capacity that brings forth the use of language, imagery, drawing, and engagement in fantasy play. Children in this stage now show the ability to think about the past and the future, but are limited by *egocentrism*, the inability to separate their own perspective from that of others. Children in this stage are unable to use the principles of logic to solve problems and consequently fail the Piagetian conservation tasks. The child's progression toward logical thinking, both in contexts referencing objects that are physically present as well as in more abstract situations, occurs during the *concrete* and *formal operational stages* from midchildhood through adolescence.

Critics of Piaget's theory point out that many of the cognitive abilities he described as occurring in late infancy and the early childhood years are actually present in much younger children. For example, numerous studies have shown that infants only a few months old show evidence of having the object concept and respond to stimuli on the basis of number and category membership, skills that were presumed by Piaget to emerge in future stages several years later. Nonetheless, Piaget's contributions to the field of cognitive development, especially in identifying the importance of the child's active role in building knowledge, are widely acknowledged.

Kohlberg's Theory of Moral Development

For Kohlberg (1927–1987), the child's ability to reason about moral issues is reflected in responses to moral dilemmas, stories in which obedience to

authority is pitted against higher level altruistic principles. Kohlberg's cognitive developmental theory posits three major stages in moral reasoning: (1) the preconventional stage (up to age 9 years), (2) conventional stage (most adolescents and adults), and (3) postconventional stage (some adults from middle age onward). The child's forward movement through these stages is precipitated by advances in thinking capacities, especially the ability to take the perspective of others, as well as opportunities to encounter conflicting points of view, particularly in exchanges with peers.

Children in the early preschool and school years are presumed to be in the *preconventional stage*. Their responses to moral dilemmas reflect an overriding concern with avoiding punishment, attaining rewards, and in general, preserving their own interests. Thus, presented with a story in which a man considers stealing a high-priced drug in order to save his wife's life, children in the preconventional stage typically state that stealing is wrong because the consequence is going to jail. Rather than referencing an abstract moral principle about the relationship of laws to the value of a human life, younger children focus on the overt consequences of the transgression. For children in the preconventional stage, the basis for moral principles resides in adult authority, and the child's own needs and desires dominate in the moral reasoning process.

As children progress beyond the preconventional stage, they move toward accepting the norms of the larger social group (the conventional stage), and ultimately toward developing individually based principles of justice and morality (the postconventional stage). While some research has found support for the existence of Kohlberg's stages, even across different cultures, other work has cast doubt on the idea that individuals of a given age respond to moral dilemmas in a manner consistent with only one stage of moral development.

Erikson's Theory of Identity Development

Erikson (1902–1994) offered a comprehensive eight-stage life span theory of personality development

that was based on individuals adapting to the developmental tasks and challenges confronting them at particular times in their lives. These demands are seen as being derived from societal values and customs that hold out specific requirements for individuals to meet, such as how infant feeding and toilet training are to proceed. At the same time, societies have developed ways of supporting individuals, such as caregiving practices and educational institutions, as they navigate the specific crises life presents them. Central to Erikson's theory is the idea of *identity development*, that at each stage, the individual seeks to more fully understand and accept the self in the context of society. The successful resolution of crises at each stage sets the foundation for positive identity development at later stages.

The first three stages of Erikson's theory most directly pertain to the period of infancy through early childhood. In the first stage, *basic trust versus mistrust* (birth to about 1 year), the young child seeks consistency and reliability in the relationship with the caregiver. If the child can trust that he or she will be fed, comforted, and cared for, and that the caregiver will return after an absence, then there is a solid basis for coping with stress and frustration in later years. In the second stage, *autonomy versus shame and doubt* (about 1 to 3 years), children's burgeoning independence may conflict with certain rules laid down by caregivers or other social agents (i.e., toilet training is expected). Being able to negotiate these conflicts with confidence and without shame can forecast positive self-esteem later in development. In the third stage, *initiative versus guilt* (about 3 to 6 years), the child zealously engages with the social world and develops interests in an initial exploration of who he or she is as a person. If the child's explorations are not thwarted by excessive social constraints, identity development will proceed in a constructive fashion.

Erikson's theory is sometimes criticized for lacking specifics about the mechanisms of development and for containing elements that are difficult to evaluate empirically. At the same time, he is recognized for acknowledging the wide-ranging factors that can influence an individual's development.

Stage theories have enjoyed tremendous popularity over the past several decades, perhaps because they capture what seem to be dramatic differences in how children behave when they are observed at two widely separated time periods. The idea of stages is clearly reflected in popular beliefs about children (e.g., in the common parental use of the term *the terrible two's*) and even appears in the names of widely used early childhood screening tools, such as the Ages & Stages Questionnaires employed by educational and health professionals to assess the typicality of children's development. However, many contemporary researchers now believe that fine-grained observations within shorter time periods reveal what is actually the continuous, and not stagelike, nature of many developmental processes.

STANDARDIZED ASSESSMENT

A standardized assessment is administered and scored in a consistent, or “standard,” manner each time the assessment is given. Standardized tests are designed such that the questions, conditions for administering, scoring procedures, and

interpretations are always consistent from child to child from time to time. In judging the quality of a standardized assessment, validity (does it test what it says it tests) and reliability (does it do it every time) are typically viewed as essential elements.

Many people erroneously assume that standardized testing means high-stakes tests, with multiple choice, computer-scored answers; limits on time for completion; and comparison-based percentile scores. Any test given in the same manner to all test takers is a standardized test. Standardized tests can be low-stakes or high-stakes tests, may or may not have time elements, have a variety of types of questions and responses, and have a variety of ways to report the outcome.

The opposite of a standardized test is a nonstandardized test. Nonstandardized testing gives substantively different tests to different test takers or gives the same test under considerably different conditions (e.g., one group is permitted far less time to complete the test than the other group), or evaluates them differently (e.g., the same answer is counted right for one student, but wrong for another student). Standardized tests are perceived by educators as being more impartial than nonstandardized tests. The consistency of standardized tests also permits more reliable comparison of outcomes across all test takers.

Background

The use of standardized testing in the United States began with the Army's Alpha and Beta tests developed by Robert Yerkes and colleagues to test recruits for World War I. The written Alpha test helped to determine who would be commissioned officers and the pictorial Beta test helped to weed out unsuitable military prospects. Immigration also contributed to the growth of standardized tests in the United States as literacy tests were used to determine new arrivals' social roles and status upon entrance to America.

The federal government's desire to make meaningful comparisons across multiple public education systems and settings also contributed to a

growth of standardized testing and eventually to the debate over usage of standardized testing. First, the 1965 federal Elementary and Secondary Education Act (ESEA) required standardized testing in public schools. This was followed by the No Child Left Behind Act, passed by Congress in 2001 and signed by President George W. Bush in 2002, which further tied public school funding to standardized testing.

Under No Child Left Behind, students in Grades 3 through 8 are given yearly tests used to assess each student's achievement within a short amount of time. Some dissenters called the act "No Child Left Untested." Many people further disagree with standardized testing, arguing that some children are not good test takers and thus do not show their true ability, that the tests are culturally biased, and that the pressure to do well causes high anxiety and stress. Another controversy surrounding standardized testing is their use in teachers' evaluations and determining merit pay leading many to argue that teachers have been required to teach to the test rather than teaching children what they actually needed to know.

Design and Scoring

Standardized testing can be composed of multiple-choice questions, true-false questions, essay questions, short-answer questions, performance-based assessments, authentic assessments, or nearly any other form of examination. Multiple-choice and true-false items are most common on standardized measures because they are scored inexpensively and quickly by computers. Standardized tests that have short-answer or essay writing components are assigned a score by trained independent evaluators who use rubrics (rules or guidelines) and benchmark papers (examples of papers for each possible score) to determine the grade to be given to a response.

Human scoring can be variable and thus problematic. For example, some believe that low-paid, unhappy employees score tests poorly. Agreement between scorers can also vary between 60% to 85%, depending on the test and the scoring session (Mondays vs. Fridays). Having two or more

scorers read each paper, and possibly a third if their scores do not agree, improves the chance of eliminating error.

There are two main types of standardized test score interpretations: a norm-referenced score and a criterion-referenced score.

Norm-referenced score interpretations compare test takers with a sample of peers (the normative group) and with each other. Students are ranked as being better or worse than other students. For example, if a student's norm-referenced score is 82, 18% of the normative group did better than that student and 81% did worse than that student. Norm-referenced test score interpretations are most often associated with traditional education in the United States.

Criterion-referenced score interpretations compare test takers with a criterion (a predetermined definition of the content knowledge expectation), regardless of the scores of others. These may also be described as standards-based assessments. Criterion-referenced score interpretations are only concerned with whether or not a student's answer is correct and/or complete; and thus, it is possible for all students to pass the test, or for all students to fail the test.

STANDARDS

Learning standards are written descriptions of the skills and knowledge that children should know and be able to do at specific ages or grade levels. In defining age or grade-level expectations, standards outline learning progressions in domains of development and subject areas. Learning standards, also referred to as *academic* or *content standards*, outline what students are expected to learn, not how they should be taught. When based on current research in child development and learning, standards can guide teachers, caregivers, and parents on developmentally appropriate content, educational objectives, and dispositions for children to acquire. This entry describes early learning and development standards for children birth through 5 years of age, K–12 learning standards, the standards-based reform movement, and concerns about and benefits of standards.

Early Learning and Development Standards

In 2002, the George W. Bush administration authorized the Good Start, Grow Smart early childhood initiative, which asked states to develop voluntary early learning guidelines in language and literacy for 3- to 5-year-olds that align with state K–12 standards. The initiative asked that the guidelines be able to be adapted to a variety of child care settings. All U.S. states and territories now have preschool standards for 3- to 5-year-olds, and most have, or are developing, standards for infants and toddlers. Standards for young children birth to age 5 are typically called early learning guidelines (ELGs) or early learning and development standards (ELDS). Individual states have used additional terms, including *foundations*, *building blocks*, and *early learning indicators of progress*. In most states, early learning guidelines are available from the state education department's website. The Administration for Children and Families, Office of Child Care has information and Web links to all U.S. states' early learning guidelines at its website. Catherine Scott-

Little and Sharon Lynn Kagan, who have extensive experience and expertise in this area, have developed a website with resources and recommendations for those writing or revising state early learning guidelines.

K–12 Learning Standards

National organizations have provided guidance in developing K–12 standards for many decades. Initially, states used the standards developed by national organizations such as the National Council of Teachers of Mathematics as a model in developing their own state standards. That changed for most states when the Council of Chief State School Officers (CCSSO) and the National Governors Association Center for Best Practices, in partnership with Achieve, a nonprofit education reform organization working with states to raise academic standards, released the Common Core State Standards for K–12 in 2010. Referred to as the Common Core, the standards were designed to help all students graduate from high school prepared for college, career, and life. The Common Core includes English language arts/literacy and mathematics.

The focus of the standards is on helping students to communicate effectively, possess strong content knowledge, value evidence and use it to support their points of view, and understand other perspectives and cultures. In order to meet the expectations of the Common Core, students need to be problem solvers who persevere until they find a solution. They need to make connections, use reasoning and proof, draw conclusions, represent their thoughts, and communicate these thoughts capably to others. In 2015, 43 states, the District of Columbia, and four territories had adopted the Common Core.

The National Research Council developed *A Framework for K–12 Science Education* in 2012 based on the research on science and learning, identifying content important for students to know. States, science educators, industry experts, and stakeholders, working in partnership with Achieve, used the framework to develop The Next Generation Science Standards (NGSS) released in

2013. Many states have now adopted these standards, and many others are considering doing so.

K–12 standards in other subject areas are still generally developed by individual states, using national guidelines as models. The National Council of Social Studies (NCSS) published the *National Curriculum Standards for Social Studies: A Framework for Teaching, Learning, and Assessment*. This document outlined 10 themes of social studies to guide states in identifying content that should be included in developing their own state standards. The National Coalition for Core Arts Standards developed the National Core Arts Standards. The standards outline a conceptual framework for arts learning for PK–12 students in dance, media arts, music, theater, and visual arts. The Society of Health and Physical Educators (SHAPE America) have national standards that define what students should know as a result of a quality physical education (K–12) and health education (PK–12), and in addition have early childhood guidelines. The International Society for Technology in Education (ISTE) has a set of standards for students that outlines the skills and knowledge that it believes students need to live productively and learn effectively in our global and digital world.

The Standards-Based Reform Movement in the United States

Although standards were being mentioned in educational literature in the early 1900s, many view the landmark report *A Nation at Risk* as the beginning of the standards-based reform movement in the United States. In this 1983 report, the National Commission on Excellence in Education called for schools to adopt more rigorous and measurable standards. This prompted many states to adopt a standards-based educational system; however, many of their standards lacked clarity and rigor.

In 1989, President George H. W. Bush and the governors of all 50 states held an education summit in Charlottesville, Virginia, and set education goals for the country designed to improve the nation's

education system. Eight of the governors, along with several federal and state legislators, formed the National Education Goals Panel, which called for the development of academic standards that would challenge students and help the country meet the goals that had been set. The panel was instrumental in the development of the National Council on Education Standards and Testing, which recommended establishing voluntary, national standards that would set high expectations, instead of minimal guidelines, which had often been the case in the past. It suggested that the standards continue to evolve with the development of new knowledge. An advisory group convened by the goals panel issued a report in 1993 titled *Promises to Keep: Creating High Standards for American Students* outlining criteria for broad-based development of useful, world-class, high standards. The U.S. Department of Education, along with other agencies and foundations, awarded grants to national organizations to develop standards in various academic areas. Goals 2000: Educate America Act was signed into law in 1994 and provided resources for states to help all students meet more challenging standards.

The No Child Left Behind Act (NCLB) of 2001 brought standards and accountability to a new level. Any state accepting the federal government's targeted financial support for low-income students was required to be accountable by measuring and reporting on academic achievement in relation to learning standards. NCLB required schools to test in reading and mathematics at Grades 3 to 8 and at least once in high school, as well as testing on science three times from 3rd to 12th grades. School-level results of these tests are available online, providing parents, lawmakers, and the public far more information about student performance than had been available in the past.

Benefits of and Concerns Regarding Standards

Standards are able to clearly delineate expectations for children at specific ages and grade levels and provide guidance for teachers, caregivers, and

parents. They have been viewed as a means of raising student achievement. Because they are written for all students, standards have the potential of helping to address the achievement gap and disparities in educational opportunities by offering a consistent, research-based set of learning goals, although those benefits have yet to be realized. However, some have argued that standards written for all children do not adequately take into account individual capabilities.

There is debate whether having national standards takes away the autonomy of states to develop their own standards, which was the norm before the advent of the Common Core and Next Generation Science standards. Proponents of national standards argue that having panels of the best minds in the country developing national standards benefits all students. They suggest that students in all parts of the country can now expect the same high-quality education and that children who move from one state to another will not have to worry about being behind. They also state that schools should be able to share and save money on educational resources such as textbooks and other curriculum materials, as well as national assessments developed by the Smarter Balanced Assessment Consortium and the Partnership for Assessment of Readiness for College and Careers (PARCC).

Concerns have been raised that the increased emphasis on standards and testing may narrow the curriculum to topics that are tested and decrease children's intrinsic interest in learning. Some recommend that other, more authentic methods of accountability be explored and include subject areas that have been ignored in previous standards testing initiatives. They also suggest that less frequent testing could provide needed data while allowing for more time for teaching and learning. There is also fear that the focus on standards will cause some schools to eliminate appropriate practices, such as time for play and outdoor activities for children.

In a joint position statement, *Early Learning Standards: Creating the Conditions for Success*, the National Association for the Education of

Young Children (NAEYC) and the National Association of Early Childhood Specialists in State Departments of Education (NAECS/SDE) suggest that standards can lead to better outcomes and opportunities for all children. However, they also point out that these benefits will only be realized if the standards (a) emphasize significant developmentally appropriate content and outcomes; (b) are developed and reviewed through informed, inclusive processes with multiple stakeholders; (c) are implemented and assessed through practices that support children's development in ethical, appropriate ways; and (d) are accompanied by a foundation of support for early childhood programs, professionals, and families.

The position statement emphasizes that standards must be written to accommodate the wide range of diversity found in children. The statement calls for developmentally appropriate, high-quality curriculum, teaching strategies, and classroom practices, which would include all areas of the curriculum, including social and emotional development and promoting positive approaches to learning. They recommend that assessments based on standards be used to benefit children and improve practice, not to sort, rank, or penalize children. For example, early learning guidelines and any accompanying assessments should be used to help individualize learning for young children, not serve as gatekeepers from kindergarten.

Most education experts agree that standards must be aligned with the rest of the instructional delivery system, including curriculum, instruction, and assessment, with high-quality standards serving as the focal point for this alignment. High-quality teacher preparation, professional development, resources, and support will also be necessary in order for standards to achieve their potential of improving student learning and achievement.

STANDARDS-BASED CURRICULUM AND ASSESSMENT

There are three major threads influencing standards for curriculum and standards-based assessment in early childhood. The threads come from legislation, policies, and practices in K–12 education; legislation, practices, and regulations particular to preschool and child care, including those involving Head Start, quality rating and improvement systems, and the Child Care and Development Block Grant; and finally, the legislation and practices for children with disabilities. Each thread must be considered in the context of both an early childhood framework and the framework of K–12 education, since the age range for early childhood is conventionally defined as birth to age 8, covering both preschool and elementary venues. Thus, the landscape for curriculum and assessment in early childhood is complex due to the various settings where young children receive care and education. Of course when young children reach school age, the settings issue becomes somewhat less complex, particularly if they are educated in public school settings.

K–12 Legislation, Policies, and Practices

The National Commission on Excellence in Education was appointed by Department of Education Secretary Terrel Bell in 1981 and charged with the task of reporting on the quality of American education by 1983. The opening

paragraph of the commission's report, *A Nation at Risk: The Imperative for School Reform*, points to the "quality" crisis in education:

Our once unchallenged preeminence in commerce, industry, science, and technological innovation is being overtaken by competitors throughout the world . . . but it is . . . [education] that undergirds American prosperity, security and civility . . . the educational foundations of our society are presently being eroded by a rising tide of mediocrity that threatens our very future as a Nation and a people. What was un-imaginable a generation ago has begun to occur. Others are matching and surpassing our educational attainments. (1983, p. 5)

The report recommended the creation of performance standards and expectations for students. While there are other points in history that called for educational reform in the 20th century, notably the era following the 1957 launch of Sputnik by the Russians, 1983 is the marker for the focus on educational standards. Thus, before the 20th century and beyond, educational reform and educational quality are always linked to workforce development and economic and global competitiveness; that is, do we have an educated citizenry that can maintain our place in the world of economic growth and global competition? If not, then what must we do for schooling to ensure success as a nation? So, it is the 1983 report that drives standards-based teaching and the evolving standards-based assessment accountability for elementary and secondary education. The report recommended the creation of performance standards and expectations for students. It articulated concerns about workforce development and economic and global competitiveness that have continued to drive the standards movement in elementary and secondary education.

Following the publication of *A Nation at Risk*, professional curriculum associations, beginning with the National Council of Teachers of Mathematics (NCTM), developed and published standards in 1989 to guide K–12 teaching. Other

professional associations followed with the publication of subject area standards. Thus, teaching principles were identified and incorporated into student texts and in curricular goals for school districts, as well as in state-developed education standards.

The large-scale use of pre/post assessment had already begun in 1965 with the passage of the Elementary and Secondary Education Act (ESEA). The funds allocated under the law to districts serving children living in poverty, children most often found to also be low achieving, were focused on remedial education, often in pullout tutoring programs, that is, children removed from the classroom for special instruction. One of the requirements for receiving funds to enrich experiences in reading and math was the requirement to document child progress with pretest and posttest measures through the Title I Evaluation and Reporting System (TIERS). Thus, the teaching–testing connection as mandated by federal legislation began. Various reports in the years following pointed to the successes and failures of programs utilizing ESEA funds to increase student achievement.

With the passage of the No Child Left Behind Act (NCLB) in 2001, the federal government required regular testing of all public school children in reading and math beginning at third grade and the development of state learning standards. The legislation also included the requirement that all children would be scoring at grade level by 2014 and that sanctions would be levied against school districts failing to improve.

The Council of Chief State School Officers and the National Governors Association in 2009 began development of the Common Core State Standards (CCSS) for English language arts and mathematics. These standards were designed to even out the uneven state standards so that all children would leave high school as college- and career-ready graduates, as well as critical thinkers and problem solvers. Between 2010 and 2012, 46 states adopted the Common Core, but by 2014, three states had dropped the standards. Some opponents of the Common Core argued that because the Obama administration had encouraged the adoption of the

standards, they amounted to federal control over education that went against the tradition of states' rights in education.

Most of the states that adopted the Common Core also participated in one of two consortia to develop tests aligned to the standards: (1) Smarter Balanced Assessment Consortium or (2) Partnership for Assessment of Readiness for College and Careers (PARCC), with a few states choosing to develop their own tests. After pilot testing, PARCC and Smarter Balanced tests were implemented in 2015. By that year, several other states decided not to use these tests. In some states, controversies surrounding the Common Core and the associated tests resulted in sizable numbers of families opting out of assessment for their children, which may skew the results.

Many critics have complained that NCLB has led to overtesting of children. Besides the annual testing required by the law, school districts gave interim tests and used the results to plan interventions for greater child success. For the consequences levied by states and school districts for not making progress in student achievement under NCLB, referred to as adequate yearly progress (AYP), could be high. These consequences included firing of whole schools' staff and reconstituting the schools under new leadership with new teachers and curricula, the loss of funding, conversion of failing schools to charter schools, and public censure through the school report card data publication in local newspapers and by state departments of education.

While the goal of NCLB was to assure increased student achievement through regular assessment documented for all to see, the high-stakes nature of the assessment created practices leading to narrowing of curriculum to a focus only on what content would be tested. The result on the part of some school districts was the use of workbooks mirroring the tests as well as overemphasis on test prep. These efforts came about because of the threat and implementation of high-stakes consequences to schools and school districts not making AYP. Since the passage of NCLB, the role of testing students in K–12 has been hotly debated with an increasing call from many quarters to

reduce testing of children to prove acquisition of skills. More recently, there have been efforts to stop the practice of trying to attach measures of teacher performance to student achievement through the value-added approach, which uses statistical methods in an attempt to show the contribution of individual teachers to students' learning. Tennessee was the first state to formally use value-added modeling of student test scores, developed by William Sanders, initially as part of a school development initiative. Later Tennessee and other states began to use teachers' value-added scores as part of teachers' evaluation.

The value-added approach of linking student achievement to the evaluation of teachers gained ground as evidence mounted that even with incentives, many children in K–12 were not making AYP. In 2009, President Obama signed into law the American Recovery and Reinvestment Act (ARRA), which was also known as the stimulus act. The legislation was

designed to stimulate the economy, support job creation, and invest in critical sectors, including education. The ARRA lays the foundation for education reform by supporting investments in innovative strategies that are most likely to lead to improved results for students, long-term gains in school and school system capacity, and increased productivity and effectiveness. (U.S. Department of Education, 2009)

With these funds, states were invited to compete for grants from the Race to the Top program. States were awarded points in the grant competition based in part on their plans for rigorous standards and assessments and systems to improve instruction, and the point system rewarded states that used value-added models to factor student test scores into teacher evaluations.

As action stalled in Congress on proposals to reauthorize ESEA, in 2011, the Education Department announced it would allow states to be released from some of the law's requirements through a waiver process. States that received the waivers were allowed to develop new measures of school

and district performance that took into account improvement on standardized test performance, and they no longer had to meet the 100% proficiency target. To receive a waiver, states had to promise to tie teacher evaluation to student test scores. At the end of 2015, Congress approved the Every Student Succeeds Act to reauthorize ESEA and replace NCLB, making the waivers moot. The new law continues annual testing in Grades 3 through 8 and once in high school, but leaves identification of failing schools and plans for dealing with them to the states. States also will decide whether and how to use test scores for teacher evaluation.

Overlapping K–12 and Early Childhood Standards Movements

Meanwhile the standards-based assessment of young children in the infant, toddler, and preschool years has an overlapping trajectory and relationship to the K–12 standards movement. In 1964, as part of the War on Poverty declared by President Lyndon B. Johnson in his inaugural address, the Office of Economic Opportunity (OEO) was created. The OEO housed special programs directed toward the elimination of poverty. Besides the ESEA, which evolved into NCLB, Head Start began in 1965 under the OEO umbrella. The history of Head Start includes the development of curricular models, such as HighScope and more recently published curricula such as *The Creative Curriculum*. However, the models initially offered less-specific curricular goals and suggested guidelines for implementation, as well as guided practice for documentation of observed child progress that was formative and meant to guide teaching. It was not until 2000 that the Office of Head Start first created the Child Development and Early Learning Framework, revised in 2010 with the stated purpose of outlining

the essential areas of development and learning that are to be used by Head Start programs to establish school readiness goals for their children, monitor children's progress, align curricula, and conduct program planning. It does not pro-

vide specific benchmarks or levels of accomplishment for children to achieve during their time in Head Start. (p. 2)

Curricula and assessment traditions in Head Start are important indicators for early childhood practice, as a whole, since research and demonstration practices generated here include large cohorts of children to inform directions for best practice for all young children. It was in 1995 that Early Head Start began, moving the implementation of child development and educational services to infants, toddlers, and pregnant mothers.

Following the publication of *A Nation at Risk*, calls came for moving kindergarten in public schools away from a play-based approach supporting the development of social-emotional, cognitive, and physical development to an academic approach with teacher-directed, workbook-based curricula so that children would be ready for “real” learning and achievement. Throughout the mid-1980s across the nation, various early childhood education advocates wrote and presented position papers on the importance of play-based curricula, which culminated in the publication by the National Association for the Education of Young Children (NAEYC)’s 1987 position statement on developmentally appropriate practice. The latest version of this statement, adopted in 2009, provides guidelines for applying a research-based focus to curricula and assessment without being prescriptive in the design, delivery, and outcomes assessment of programs.

The principles behind NAEYC’s position statement support assessment of child progress, but in a holistic manner. This position places developmentally appropriate practice in an antithetical position toward outcomes-based standardized assessment practiced in K–12 schools. While NAEYC’s developmentally appropriate practice position statements have evolved since 1987 to include a perspective on standardized assessment, the principles remain in favor of naturalistic assessment of young children.

Meanwhile at a 1989 education summit in Charlottesville, Virginia, governors from all 50

states and President George H. W. Bush proposed an educational reform program called Goals 2000. The program set goals that were to be met by the year 2000. Goal 1 states,

All children in America will start school ready to learn. The objectives for this goal are that (i) all children would have access to high-quality and developmentally appropriate preschool programs . . . ; (ii) every parent . . . will be a child's first teacher and devote time each day to helping such parent's preschool child learn . . . ; (iii) children will receive the nutrition, physical activity experiences, and health care needed to arrive at school with healthy minds and bodies. . . .

This goal was often interpreted to mean that children in preschool and kindergarten should begin to learn letters, numbers, and other artifacts of the paper/pencil world of elementary school. The early childhood professional field argued that the most important part of Goal 1 was the third subgoal, which focused on health and well-being. Nevertheless, early childhood educators continued to push for a holistic approach to education by using standards to guide curriculum and formative assessment to document progress. One notable portfolio assessment system, the Work Sampling System (WSS), was "designed to enhance the process of observation and to ensure the reliability and consistency of teacher's observations" (Dichtelmiller, Jablon, Marsden, & Meisels, 2001, p. vii). The WSS provides outcomes for both curricular and developmental indicators, thus modeling the collection of data on young children to document both developmental and academic progress.

Yet, the before-school-age landscape of child care continues to be fragmented and only recently has focused on promoting quality as well as access for families seeking child care programs. Beginning in the 1990s, quality rating and improvement systems (QRISs) provided a way for states and communities to rate child care centers on quality and to reward those with higher public subsidy payments for excellence.

Besides the rating systems, states have initiated professional development systems for teachers in child care centers so that there is a ladder to credentials, including teacher licensure. Professional development credit is offered for basic child development knowledge acquired by seminars and college courses. Curriculum standards and outcomes assessment, while a part of the preparation offered in these basic orientations to the field, often stand in line behind foci on safety, child management, and such things as organization of space and creation of activities for learning. Therefore in the infant, toddler, and preschool years, standards-based teaching and assessment does not receive uniform attention in practice. However, early learning standards are found in all states with varying content and focus on academics.

These standards came about due to federal initiatives such as Good Start Grow Smart, which the George W. Bush administration launched in 2002, and guidelines for the Child Care and Development Block Grant (CCDBG). In 2014, the CCDBG was reauthorized and revised to expand child care quality efforts. Thirty-six states now include curriculum indicators as part of their QRISs, usually with alignment to early learning standards. Thus, alignment with learning standards is still a work in progress in child care centers. Those centers and home care situations seeking higher quality ratings may show that they implement programs aligned with early learning standards.

Early Childhood Special Education

The third thread in curriculum standards and outcomes assessment comes from early childhood special education history and tradition. Young children with disabilities were historically served in health care facilities and in special schools and institutions. With the enactment of the Education for All Handicapped Children Act in 1975, later reauthorized as the Individuals with Disabilities Education Act, a free and appropriate education was guaranteed to all school-age children, including those with disabilities. The act included specifications for assessment in the child's primary

language and the requirement that children with special needs be educated in the least restrictive environment possible, which ultimately led to many disabled children being educated alongside their nondisabled peers in regular classrooms. In 1986, the law was amended to include infants and toddlers, for whom are developed individualized plans based on family priorities that are known as individualized family services plans (IFSP).

Special education is rooted in a philosophy of identifying child strengths and deficits through assessment and the provision of intervention to address the specialized needs of young children. The Division for Early Childhood (DEC) prepared *DEC Recommended Practices in Early Intervention/Early Childhood Special Education* to guide assessment and intervention with young children. Besides individualized instruction, direct teaching of skills, and data-based teaching (teaching practice based on assessment), the DEC recommends that early intervention occur in the natural environment whether that is home, child care center, or school.

ZERO TO THREE was established in 1977 as a multidisciplinary organization with a focus on child development, health, and mental health in the birth to 3 populations. ZERO TO THREE published a diagnostic guideline in 1994 to supplement the established diagnostic manual used by clinicians. Both the original guideline and the revision assist teachers in understanding infant's, toddler's, and young children's special needs, but do not provide curriculum and assessment standards. Early childhood teachers must be able to apply specialized assessment and instructional techniques in all settings for young children with special needs.

Drawing Conclusions From the Various Threads

At the same time as the assessment and standards work in K–12 and early childhood education described earlier, there were calls for greater attention to accountability for educational attainment in postsecondary education and efforts to align education systems from prekindergarten through college. The Partnership for 21st Century Learning

(P21) was founded in 2002 and as of 2015 included 19 state partners. The mission of this organization is

to serve as catalyst for 21st century learning to build collaborative partnerships among education, business, community and government leaders so that all learners acquire the knowledge and skills they need to thrive in a world where change is constant and learning never stops. (n.p.)

This framework uses similar language to that in the Common Core with an emphasis on curricula that promote critical thinking and problem solving. The assessment framework calls for “a balance of assessments, including high-quality standardized testing along with effective classroom formative and summative assessments” (P21, n.d.). Traditional early childhood practice with a focus on the whole child in the family and cultural context fits well with this 21st-century framework.

Besides the importance of a P21 framework, educators must adapt curricula to respond to the United States becoming more culturally, socially, and linguistically diverse. Thus, the work begun in 2002 by the WIDA consortium becomes critical for early childhood educators to consider. In 2014, WIDA released Early English Language Standards that are aligned to multiple states' English language standards and the Head Start framework so that curriculum and assessment in early childhood can be holistic in its approach to facilitating learning for the fastest growing population of young children—English learners.

While early childhood educators have been players in developing, interpreting, and using standards-based curriculum and assessment, the approach is dominated by K–12 philosophies, legislation, and state and federal priorities. Notable exceptions include work to make early childhood standards include a focus on health and well-being, to stop the practice of redshirting as a response to the increased academic focus of kindergarten while also recommending changes to

how kindergarten is taught, and the development of QRISs.

Early childhood advocates won a battle during debate over Goals 2000 to include the underlying health and well-being of students as the focus of readiness for school in Goal 1, rather than *readiness* being defined merely as “being ready to read.” Early childhood leaders advocated that being ready for literacy instruction presupposed adequate food, housing, and access to health care so that young children could come to school ready to learn. These advocacy efforts also stressed the holistic nature of curriculum through intentional teaching and developmentally appropriate practice.

Kindergarten redshirting occurs when families hold back their 5-year-olds so they will be more mature and able to sit still and manipulate pencils on paper. The position statements that NAEYC and its state and local affiliates began to issue during the 1980s on developmentally appropriate practice concentrated on active learning standards in contrast to the increasing reliance on paper and pencil tasks in kindergarten; redshirting should be unnecessary when curricula are developmentally appropriate. Developmentally appropriate practice starts with the child in the social and cultural context of the school or child care center. NAEYC’s publications discuss ways of teaching based on solid research and an emphasis on curricula and assessment promoting critical thinking, self-empowered learning, and holistic understanding of the knowledge, skills, and dispositions required to be a lifelong learner.

Finally, the development of QRISs, with their focus on child care settings, professional development for teachers, and guidelines for curriculum and assessment standards and strategies, promises access to a high-quality learning experience for all young children.

STATE POLICY MAKING

Developing and implementing early childhood policy is complex but done well can have a profound impact on the trajectory of growth for all children. Challenging factors that contribute to this complexity include the multiple contexts in which children access early childhood services, level of local and state commitment to collaboration, navigating state configurations of early childhood systems, and cultivating leaders with early childhood competencies. State policy should support children to move seamlessly through the birth through age 8 continuum known as early childhood. This entry addresses the multifaceted structure of early childhood state policy making.

Collective Impact

The early childhood research is clear: How adults, communities, and state governments act impacts the developing brain. The Center on the Developing Child at Harvard University authored *A Science-Based Framework for Early Childhood Policy: Using Evidence to Improve Outcomes in Learning, Behavior, and Health for Vulnerable Children* in 2007. The findings suggest that multiple interrelated factors influence children's developing brains and that coordinated effort by adults, communities, and state government can collectively impact a positive trajectory of development.

To act upon the knowledge that neuroscience provides, a comprehensive systems approach that accounts for family, community, and government accountability to be intentionally engaged in the

lives of children is needed to make a collective impact toward supporting a continuum of growth for all children. Efforts are dependent upon how well state and local governments set policy and coordinate services in the context of local and state political climates. In order to support a seamless continuum of growth for all children ages birth through 8, all communities and state agencies should consider policy development that broadly addresses the needs of all children and families. Some examples of policy decisions states face are

- where children are being served when not in the care of their families,
- how to measure the quality of early care and education services across settings,
- what criteria comprise a highly qualified teacher, and are teachers considered to be compensated and qualified in the same way across all settings; and
- what early learning standards and curricula are most effective and are they effective across all settings?

These are just a few policy questions that challenge states. The complexity of local and state government processes and vision about early childhood can often be a barrier to developing and implementing well-coordinated comprehensive early childhood policy. However, initiatives such as the PreK–3rd Grade National Work Group, the National P3 Center, and the BUILD Initiative are helping states navigate paths toward a coordinated effort for comprehensive policy development.

Complexity of Early Childhood Systems

Children ages birth to 5 will most likely spend a significant amount of time in at least one or more settings outside of their home. In 2012, Child Trends Data Bank reported more than 60% of children within this age range will be in the care of someone other than their parent(s). Their early care and education will be provided by individuals who are relatives, own a family child care business,

teach in a center-based program that may or may not be funded by federal or state dollars, are home visitors or interventionists, or teach in public or private schools. Because individuals with diverse experience and educational backgrounds serve young children in a variety of settings, developing state policy that can reach all settings that serve young children is challenging.

Comprehensive and inclusive state policy can support the premise that every child age birth through 8 in every setting deserves high-quality care and education. State statutes that regulate agencies and their scope can be a barrier to developing comprehensive and inclusive policies. We often see policies emerge from individual state agencies that may have a particular lens on early childhood, have purview over specific settings due to funding sources, or have a narrow scope of a particular age group. For example, a health agency may make health policy separate from an education agency or from a child welfare agency. An education agency may have one or more state-funded programs with differing policies serving the same ages. The Early Childhood Systems Work Group, a collaboration of national organizations focused on early childhood system-building issues, in 2011 outlined a systems framework inclusive of health, early learning and development, and family leadership and support that lead to thriving children and families. Consensus on the primary goal will help states form the collaboration needed to coproduce effective policy.

Multiple funding sources utilized by states compound the complexity of comprehensive early childhood policy making. Federal initiatives such as Head Start; the Child Care and Development Block Grant; Maternal, Infant, and Early Childhood Home Visiting (MIECHV); the Individuals with Disabilities Education Act Part B and C; Race to the Top Early Learning Challenge; and Preschool Development and Expansion Grants as well as state initiatives such as state pre-K programs each have their own standards. Funds are not often situated within a single state entity to manage and coordinate but instead are located across multiple agencies. The fragmentation of funds across state agencies adds a challenging

layer to building early childhood systems within existing state configurations.

State and Local Early Childhood Configurations

The BUILD Initiative has reviewed state governance models and provides strategies on state governance design. States work within coordinated, consolidated, or, in a few cases, independent agencies dedicated to early childhood. Regardless of the model, partnerships between agencies and local communities are necessary to really develop comprehensive early childhood policy that makes a difference. In BUILD's January 2014 publication *The Nuts and Bolts of Building Early Childhood Systems Through State/Local Initiatives*, components and benchmarks for developing connections provide states with details on how to begin addressing the work of collaboration. One of the key lessons learned during the study of states engaging in a BUILD collaborative was that the agreed-upon vision of the collaborative should be broad, not narrowly focused on any particular element of early childhood.

The Improving Head Start Readiness Act of 2007 required states accepting federal Head Start funds to convene a state advisory council. These councils are representative of state and local government early childhood stakeholders charged with addressing a broad array of early childhood system components. To encourage buy-in, the funds provided to states needed to be matched by state and local entities. Although these funds did not create the concept of Children's Councils, as local or state entities that coordinate services, they did bring early childhood entities together with a focus to address comprehensive strategies for uncoupling fragmented systems and make recommendations for comprehensive, cross-sector policies to benefit young children and their families. It was reported by Head Start that many states went beyond the required membership to include key partners at the local level. Although the funding has ended, states must maintain their councils, though it remains unclear the extent to which the activity of the

councils will remain focused. Other examples of collaborative efforts have emerged from states.

The Foundation for Child Development provides resources on current research that has implications for policy and practice. Notably, an article highlighted by the foundation featured New Jersey's advocacy efforts to recommend comprehensive policy shifts in the areas of teacher education, guidance on the use of assessment, transition to kindergarten, and mandating full-day kindergarten. The July 2014 article *Strong Early Learning Systems = Strong Young Readers: New Jersey's Action Plan for Success* by the Advocates for Children of New Jersey provides a succinct description of purpose, rationale, and recommendations, and highlights Washington State's example of collaboration.

Leadership

Regardless of state configurations that govern early childhood state policy development or management of state and federal funds, knowledgeable and engaged leadership at every level is the key to actualizing comprehensive early childhood state policy. The National Governors Association is one resource to assist governors with navigating the literature related to early childhood and providing links to resources for best practices. However, a gap remains to provide government leaders with a leadership framework that asserts the principles and practices needed for coproduction of comprehensive early childhood policy.

Leadership organizations such as the National Association of Elementary School Principals have boldly stepped out and provided a competency framework for school leaders. The 2014 publication *Leading Pre-K–3 Learning Communities: Competencies for Effective Principal Practice* outlines six competency areas. Of particular importance is the first competency area, which calls for a disposition to embrace the continuum of development and to think of a learning community as internal and external stakeholders, inclusive of parents. Competencies such as these support the underlying foundations of comprehensive policy

development: a shared understanding of a vision, and that collective collaboration will help navigate through the fragmentation of early childhood systems toward unified policy that can have positive effects for all children across all settings.

Conclusion

States struggle to move beyond a fragmented system of collaboration to true coproduction of comprehensive state policy. The term *coproduction* is not new but perhaps needs some revisiting in the context of early childhood. The idea behind coproduction is to engage all parties, especially the recipients of the service, in policy development. States are fortunate to have access to multiple partners that can arm states with the latest research, trends, and data to inform policy makers and partner in creating effective policy. Examples of state partners are Administration of Children and Families Office of Child Care and Office of Head Start, BUILD Initiative, Center on Enhancing Early Learning Outcomes, Council of Chief State School Officers, Center for Law and Social Policy, Center on the Developing Child at Harvard University, Education Development Center, Foundation for Child Development, National Association for the Education of Young Children, National Association of Early Childhood Specialists in State Departments of Education, National Association of Elementary School Principals, National Governors Association, National Institute for Early Education Research, National Women's Law Center, and others.

STORYTELLING AND STORY ACTING

Storytelling occurs in a variety of forms, one of which is early childhood classroom communities. Vivian Paley's storytelling and story acting process is used in classrooms across the nation and internationally to support young children's social, emotional, cognitive, language, and literacy development. The storytelling and story acting processes are often integrated into the school curriculum. The only supplies necessary for this activity are paper and pencil. Storytelling is voluntary and self-initiated; children choose to tell a story during center or choice time, and narrate any kind of story they prefer, with any type and number of characters, pretend or real. Children dictate their stories to a transcriber, and the transcriber records the children's stories verbatim. An example of a story told by a 48-month-old girl follows:

Once upon a time there was a beautiful princess and her name was Aurora and there was a unicorn and that was her friend and there was beautiful water with sparkles in it and a little animal was stuck in it. A princess saw the little animal and she didn't know the prince was there. And then the little animal got out because Aurora helped the animal out of the water. There was a dinosaur, they ran so fast, the dinosaur didn't get them, the unicorn flew into the sky. They got a beautiful castle and the prince was there and they got married. The End.

Storytelling dramas are activities in which children act out their own stories in a group. On the same day children have told their stories, the stories are acted out. The teacher reads through the story first; then children (or the teacher) choose

their classmates as actors to dramatize the stories while the remaining class members serve as the audience for the drama. There is no rehearsal for the story acting. Both boys and girls find it highly motivating to tell their stories, based on interests and knowledge, and act them out. The combined practice of both storytelling and story acting seems critical to the success and educational effectiveness of the practice. Children tell their stories knowing that their stories will be shared with their peers during the dramatizations. Furthermore, storytelling and the subsequent dramatizations involve play, creativity, and social experiences, making them powerful and motivating opportunities to develop skills in an authentic, fun, child-centered activity.

Research on Storytelling and Story Acting

Child-created stories are examined in research across a number of fields such as psychology, education, and linguistics. Children's stories reveal something important about who they are and how they see the world. Storytelling can be a tool for educators to understand children in depth and better meet their interests and needs. Story acting brings together the entire classroom community in a child-led and adult-structured shared drama activity.

Most research on children's storytelling focuses on the content of children's narratives and the narrative form, with the focus most often being the stories themselves. This research demonstrates that children's stories reveal important information about children's development of voice and narrative understanding and conceptions of people, which are culturally shaped and different across boys and girls, and their understanding of the world.

Furthermore, storytelling and story acting engages children with authentic opportunities to engage in the subskills of early literacy development, including oral language vocabulary and syntax, knowledge of narrative form, conventions of print, phonemic awareness, and comprehension, with the teacher scaffolding the children's

learning. A comparison of similar children exposed to a traditional skills-based literacy approach to those taught with a storytelling and story acting curriculum showed that the children who participated in the storytelling and story acting curriculum showed significant gains in both vocabulary and literacy skills.

Storytelling and story acting also provide a connection between the contextualized speech of young children and the decontextualized language that occurs in books and writing. Contextualized language is that which a child learns in a familiar place, doing familiar activities, such that the conversational context helps the child learn any new words that arise. Decontextualized language is more difficult to understand because it is abstract and the meaning comes mainly through linguistic cues. Both listening to and telling stories provides a bridge between contextualized and decontextualized language in that the story itself provides greater context to the words and their symbolic meaning.

Although most research on dramatic play has been conducted in dramatic play centers in which children come and go, and interact in dyads or triads, a few studies have examined story acting based on children's stories in a whole-group setting. Story acting allows children to portray their thoughts and feelings, as well as connect to other children's stories. Story dramas integrate physical motor skills with art and social interaction skills.

Acting out the stories can be an avenue for building a sense of community in the classroom. Community building emerges through several processes associated with the storytelling and story acting curriculum. First, each child has an important role to play, including the roles of storyteller, audience, and actor. These roles provide opportunities for children to contribute to the classroom community. The storyteller role provides leadership opportunities, in which children often direct the actors in their performance. Audience members show self-regulation skills to maintain attention and provide support and positive feedback to their classmates. Actors rely on self-restraint to avoid hitting or kicking their classmates in the pretend

fight that often occurs. Actors also have the opportunity to play the role of opposite gender characters, giving the children models of greater flexibility in gender roles.

Regardless of developmental level, all children are able to participate in the storytelling dramas, providing them the opportunity to learn about other peers in the classroom and see and appreciate the qualities that each child brings. The shared public arena provided by storytelling and story acting provides opportunities for children to share humor, work together to accomplish the task of acting out the story, and build relationships with one another. One way children express this appreciation of others is by adopting peer strategies and ideas as their own. Children often imitate the themes of other children's stories and repeat themes that were well received by the audience of peers.

Storytelling and story acting can also increase children's confidence and provide a sense of belonging and social engagement. Story acting requires emotion and self-regulation. For example, when dramatizing, children practice waiting, taking turns, and not touching others during pretend action. Children's stories often include themes of aggression and power, and stories can be an outlet for children to explore these emotions that are often taboo or forbidden in home and school environments.

Children of differing abilities and development often participate in the storytelling drama activity. Because this activity is child centered and follows children's interests, it is effective with children at various abilities. Participation in story acting allows peers to view children with developmental challenges in a positive light and focuses on individual strengths as contributing to the classroom community. Moreover, story acting provides children with an outlet to express complex emotions such as anger and aggression in a safe context. The audience of both peers and teachers is more accepting of exploring these difficult emotions when in the pretend setting of the story and acting.

Storytelling, as a choice during learning centers, and story acting, during whole-group time and done for an age-appropriate length of time,

presents a unique opportunity during the classroom day where children come together as a group to build relationships, participate and collaborate, and value each individual's strengths to develop a sense of belonging to a community. Storytelling and story acting incorporate the pretend play that children thrive on, but yet include the ideas, participation, and cooperation of the class as a whole group to build community.

Implications for Practice

Implementing storytelling and story acting within a developmentally appropriate early childhood curriculum can transform children's narrative, social, and emotional abilities over the course of a year. Teacher guidance is important to scaffold the learning process, to help form the narrative structure, and to set boundaries for the acting process. The teacher's role in the dictation varies in that some teachers take the dictation verbatim, and others provide gentle prompts to scaffold the child's narrative. Care must be taken not to ask so many questions that the child's ownership of the story is undermined or that the child feels criticized. Over time, children take ownership and can lead the activity, as essential for the growth of narrative, group membership, sharing of roles and responsibilities, and practicing "story" scenarios in a safe space. Teachers can support children's storytelling and story acting by providing time, space, and agreed-upon rules.

The teacher's most valuable contribution to the activity is listening for and acknowledging shared story themes, experiences, and cooperative behavior among the classroom group. Teachers can also provide supports for children with special needs or children learning English who might otherwise have difficulty expressing a story. Supports might include celebrating single word or very short stories, providing visual props, modeling stories, providing prompts based on listening, and listening for stories in other areas such as the dramatic play area for children who are reluctant to tell stories. Children may become more comfortable telling their own stories over time, but all children play an

important role as an audience member or actor during the dramatization. Teachers should expect that children often tell stories with common themes; this repetition is not cause for concern, and may be necessary practice for children who are just learning this narrative form.

One common area of challenge for teachers is the aggression portrayed in many children's stories. Teachers may be uncomfortable with the aggression and violence and may be conflicted about children acting out aggressive stories in the classroom. One view is that this type of aggression should not be tolerated because it provides models of unacceptable behavior and may encourage further aggression. The contrasting developmental view is that it is important that children learn that they can explore aggression and anger in a safe environment and regulate the outcomes themselves. Pretend aggression can be a positive way to explore and regulate strong emotions.

STRENGTHS-BASED EDUCATION AND PRACTICES

Strengths-based education and practice (SBEP) is a conceptual perspective and approach that promotes identification and appreciation of individual, group, and community interests, goals, and strengths through active, collaborative partnerships. Professionals who implement this approach assume that every individual, family, school, and community has power and resources to resolve challenges, achieve goals, learn, and thrive. SBEP comprises a supportive environment in which stakeholders have opportunities for reflective practice, learning, relationship building, and assessment of both assets and challenges. This entry provides an overview of the essential elements of SBEP as well as its historical context, theoretical foundations, and applications to early childhood education (ECE) programs.

Overview

Positive relationships among children, teachers, and families based on trust, respect, and collaboration are vital to successful SBEP in ECE programs. Within the context of such relationships, there are opportunities for support and resources, the acquisition of new perspectives, collaborative evaluation, and problem solving. Practices that support SBEP include integrated teaching and learning approaches, reflective practice, cultural sensitivity, and inclusion. Underlying these practices is the notion that people are active agents in improving their own lives.

SBEP has the potential to benefit individuals, programs, and communities. For children, SBEP

facilitates positive identity development, social-emotional competence, physical and mental health, creativity, and academic success. SBEP encourages children to recognize and accept their strengths and limitations, empowers them to participate in their own learning, validates their individual expression and roles in the community, encourages responsibility and accountability, and promotes effective decision making.

SBEP empowers families to explore their children's strengths, possibly altering their understanding and expectations of their children. This shift in perspective has implications for how families support, teach, and nurture their children. Professionals and schools that utilize SBEP seek to reinforce families' competencies, contributing to their sense of satisfaction, importance, and well-being as parents—factors that support positive parent-child relationships, parents' capacity to resolve family conflicts, and parents' role as children's first teachers. SBEP supports families' motivation, participation, and decision making in their children's education.

SBEP is advantageous for ECE teachers, equipping them with skills to establish positive, sensitive, and nurturing relationships with children and families, to individualize their teaching methods, to implement curriculum in innovative ways, and to meet standards for high-quality practice. Engagement in ongoing strengths-based reflective practice enhances teachers' awareness of their own and others' knowledge, skills, backgrounds, and biases.

Other individuals from schools and communities that contribute to children's learning and success may also use SBEP. A critical component of effective SBEP is the alignment of all professionals in this approach, including ongoing collaboration, as an integrated system. When professionals in the community use SBEP with each other, they foster alliances, form common goals, and share information and resources. SBEP can facilitate community engagement and promote a "collective impact approach" in education whereby teachers, families, and community members align to celebrate individual and collective strengths, focus on

improvement and goal setting, and share accountability. A SBEP infrastructure is essential for continuous quality improvement of ECE.

Historical and Theoretical Underpinnings of SBEP

The underlying principles of SBEP in ECE stem from a number of mental health and social service fields. Strengths-based practice first emerged in the field of social work as an alternative to traditional, deficits-based practice, which focused on individual pathology. The social work tenets of social justice, self-determinism, and empowerment underlie the most basic principle of SBEP, namely, that every individual, family, group, and community has both internal and external resources that can be mobilized to support healthy development, to overcome adversity, and to achieve success in different life domains.

Whereas traditional notions of helping and educating others focused on problems with individuals, a strengths-based approach envisions helping and educating as a process of empowerment, in which the professional engages with individuals, groups, or families to identify and enhance existing strengths. Strengths-based practitioners deliberately prioritize the beliefs, values, and worldviews of individuals and families. This approach stands in stark contrast to deficits-based models that position service providers as "experts" whose job it is to identify problems and offer strategies for "fixing" them.

SBEP in education and social service models emerged in the early 20th century with Mary Richmond and "friendly visitors" from the Charitable Organization Society, who held that poverty was not a moral shortcoming; instead, problems in individuals, families, and communities should be understood in the context of challenging social conditions. Concurrently, the professionalization of helping, formalization of social work education and training, and adaptation of "social diagnosis" from medicine helped consolidate and launch SBEP, eventually leading to its integration in ECE.

The late 20th century ushered in several other frameworks and theories that helped to popularize SBEP across fields of practice. In 1990, the Search Institute introduced Developmental Assets—an identified set of skills, experiences, relationships, and behaviors that enable children to develop into successful adults. Several years later, Dennis Saleebey and colleagues at the University of Kansas codified a strengths-based approach in social work. This approach emphasized that (a) every individual, group, family, and community has strengths; (b) adversities can provide opportunities for growth; (c) people's ambitions and capacities for growth and change should be recognized and taken seriously; (d) individuals are best served through collaboration; (e) all environments have resources; and (f) care is essential to well-being.

Later that decade, the American Psychological Association began to promote positive psychology as a field of scientific study, focusing on individual strengths. Simultaneously, the field of positive youth development (PYD) also gained prominence, highlighting the capacity of youth to make positive contributions to self, family, community, and society. In education, whole child initiatives have underscored PYD, shifting from a narrow focus on academic success to broader notions of positive child development.

The scientific study of resilience made substantial contributions to SBEP. Around 1970, psychologists first began to conduct research on positive adaptation to adversity, or resilience, observing children who were exposed to biological and psychosocial risks (e.g., parental mental illness, poverty, trauma) and exhibited positive adaptation. Most experts have come to understand resilience as a product of dynamic interactions among risk and protective processes operating at multiple levels (individual, family, community, societal) rather than as an individual trait. Resilience research has informed how professionals identify risk and protective factors and foster positive child development.

Last, SBEP in ECE has roots in special education and early intervention. Carl Dunst, Carol Trivette, and Angela Deal have conducted

important research on early intervention and on family-centered practices, which emphasize families' rights to make decisions on behalf of their children and to be treated with respect.

SBEP in ECE

A number of ECE programs have implemented SBEP, but some programs are noteworthy. For example, Head Start (HS), a dual-generation program supporting low-income children and families initiated in the 1960s, advocated that parent involvement and support were paramount to children's success and school readiness. HS programs require SBEP in ongoing assessment and inclusion of families from diverse backgrounds. In the 1990s, HS began to make particular use of parent empowerment theories, viewing parents as partners and as experts on their own children. More recently, technical assistance initiatives, such as the Office of Head Start's National Center on Parent, Family, and Community Engagement, highlight the importance of forming positive goal-oriented relationships with families.

HS and other ECE programs have implemented a number of formal SBEP initiatives as well, including Strengthening Families, which emphasizes protective and promotive factors in supporting parents as partners, providing knowledge of child development, and helping parents develop social connections. Other SBEP approaches in ECE include Reggio Emilia and HighScope, which seek to build on children's own unique interests, skills, and strengths.

SBEP in ECE focuses on mutually supportive relationships with an emphasis on family engagement—how programs engage families in the program—rather than solely on parent education and participation in the program. This focus values parents' expertise on their own children and their self-efficacy in accomplishing their goals, rather than exclusively focusing on their challenges. SBEP in ECE also stresses that every child and family has strengths, skills, and capacities that can be utilized to help them achieve their goals.

Cultural competency among ECE professionals is another important component of SBEP, including an appreciation for the unique traditions, practices, and worldviews of children and families, and a recognition and respect for children's individual rights, abilities, interests, learning differences, and preferences for activities and routines. The National Association for the Education of Young Children's standards for professional preparation, for example, highlight the importance of inclusion, respecting diversity, strong family and community relationships, and respecting cultural variations in families' values.

Strategies to Support Family Partnerships in ECE

Partnerships with families, based on trust, collaboration, and respect, characterize SBEP in ECE. Ongoing and open two-way communication through everyday conversations, parent-teacher conferences, daily journals, written notes, message boards, e-mails, home visits, and participation in program activities are several methods that parents and teachers may use to communicate about child and family strengths and to share family customs and traditions. Parent-teacher partnerships also often involve collaborative assessment and goal setting for children. Families provide critical information about their children and themselves supporting the review of data around child assessment and program improvement.

Strengths-Based Approaches to Curriculum and Assessment in ECE

A number of ECE approaches (e.g., Reggio Emilia and HighScope) encourage teachers to use documentation (a) as a way to connect with families and illustrate children's progress and (b) as a vehicle for professional development in which teachers can share and reflect on their work with one another. SBEP strategies to document, understand, and assess children's strengths and needs include portfolios of artwork or writing, videos, photographs,

observations and recorded anecdotes, and more formal assessments. For children with special needs, programs often use individualized education programs to set goals and assess children's strengths, needs, and progress. Strengths-based assessment approaches focus on the whole child and his or her unique capabilities. Gathering observations, data, and anecdotes of children's interactions with teachers, peers, and materials provides the opportunity to document their distinct experiences, interests, and learning styles. Programs can use this information to plan activities, transitions, and curriculum. Strengths-based assessment also provides useful information to programs on how to build an environment supportive of child, family, staff, and community strengths, creating a culture of respect, trust, and appreciation.

Evaluating SBEP

Several tools exist to help programs evaluate their SBEP. Examples include Beth Green's Strengths-Based Practices Inventory, the National Center for Community-Based Child Abuse Prevention's Protective Factors Survey, and Search Institute's Developmental Assets. These measures focus on a program's ability to empower children and families through supportive relationships by building on existing characteristics, skills, and competencies, and by recognizing resources in the community.

Conclusion

Given the capacity of SBEP to promote children's early learning and development, as well as family, program, and community strengths, it is not surprising that SBEP in ECE has become more common. SBEP grows out of a rich tradition of celebrating diversity and strengths across many fields of practice, including social work, resilience, positive psychology, and PYD. Strengths-based ECE programs value relationships with families, cultural competency, reflective practice, and individualized approaches to child assessment. Evaluation of SBEP is relatively new, but several

tools exist for helping ECE programs engage in quality improvement around SBEP.

STRESS AND RESILIENCE IN FAMILIES

Stress and resilience in families are natural dynamic processes that help families, as biosocial systems within complex ecologies, to balance the changing

needs of individual family members as well as preserve and strengthen the family as a unit. The terms *stress* and *resilience* represent constructs used in scientific studies and the development and implementation of early childhood and family support programs. A developmental framework known as applied biosocial contextual development (ABCD) identifies both stressors and promotive processes as essential for children to develop resilience. When a family experiences stressors, this provides natural opportunities for young children to learn about strategies to counteract stress and, in turn, foster resilience. At the same time, when stressors become excessive or chronic, they can harm children and the family unit. The ABCD conceptual framework is compatible with the view that early adverse events can impair a child's physical, psychosocial, and cognitive development and produce lifelong negative health effects. In the ABCD model, as well as other epigenetic frameworks, behavior and development are viewed as intertwined with basic biological processes and the expression (or inhibition) of genes. For families with high levels of stress and low resiliency, some of the most important interlinked biological outcomes are (a) structural and functional changes to the child's brain that reflect inadequate levels of cognitive and social-emotional stimulation and learning; (b) a profile of biomarkers predictive of elevated risk for early onset of cardiometabolic disorders strongly linked to chronic stress; and (c) increased prevalence of respiratory and allergy conditions associated with exposure to environmental toxins, lack of adequate exercise and nutrition, and chaotic households.

Definition of Terms

Family resilience is a psychological construct that encompasses many dimensions of how families function. The essence of resilience is that families have a repertoire of approaches to help them survive—and even benefit from—the ebb and flow of challenges they encounter. The construct of resilience is strongly linked to the field of positive psychology and to understanding the biosocial

nature of human development itself. In times of duress, families demonstrate their resilience; in times of calm, families may reflect on how they handle difficult periods and even take actions so that they are well prepared to be resilient in the face of future adversity.

Families are the primary stable providers of the young child's physical, social, emotional, and cognitive environment—the socioecological context that can protect and nurture children during the time of exceptional dependence on others for survival. Families also serve as major facilitators of children's learning about the world and themselves as active agents in the world. Many of young children's experiences, direct and indirect or observational, within their own family environment provide the basis for how they negotiate with others outside the family. Above all, promotive families offer a trustworthy, caring haven where children can readily obtain help understand their own experiences and have their emerging needs met.

The specific behaviors that comprise a promotive family, however, are hypothesized to vary as a function of the particular stressors a family faces, the resources the family has available, and the stage in the life of the family and the child. That is, specific behaviors that are promotive for a given family or culture at a given time and place in history may not necessarily be promotive for families living in other places or at other times in history. This relativity principle about promotive and resilience strategies is vital in conducting research and working with families to understand and improve effective problem solving.

As goal-directed social units that fulfill core societal functions, families act to maximize the health of their children and their progress toward becoming competent, caring, and contributing adult members of society. At the same time, most families value interdependence and positive relationships within the family. Interdependence is not inherently at odds with children becoming independent and autonomous later. Rather, interdependency is a complementary dimension of mature behavior that fosters efficiency and can promote

flexibility, planning, and problem solving for the family as a unit. Families recognize that with increasing age and experiences, children will form new and lasting social relationships in multiple realms of personal, work, recreational, and community life; these later relationships also will benefit from healthy forms of interdependence.

Another important family goal is that their own values, traditions, and history are shared and passed on through the generations. For some families, this goal may be explicit and openly discussed; for others, this goal may be implicit or embedded within the family's encouragement that their children become "good people" and "show respect for their family's heritage." To achieve this goal of sustaining the identity of a family through the generations, many families tell stories about how their ancestors and older family members have survived difficult situations (i.e., a resilience repository). These shared memories reveal strategies for maintaining equilibrium when families face threats. These intergenerational reflections provide families with opportunities to think about how best to adapt to their current life situation and how to strengthen future resilience. Conversely, families that minimize, overlook, or actively deny the reality of "difficult times" may be limiting their children's opportunities to acquire strategies that build subsequent individual or collective group resilience. Within a community, there may be many rituals, songs, literary works, and community-endorsed messages and activities that can serve to reinforce the within-family resilience messages. For families in relatively isolated places or for those who have been victims of marginalization, racism, rampant disease, or relocation due to extreme conditions, their young children may lack this natural form of reinforcement from the wider community and from children in other families.

Stress refers to a collection of highly diverse conditions that increase the demands on the family and the individuals within the family to maintain equilibrium. *Family stress* often connotes that the family unit is undergoing a period of vulnerability, ranging from stress in meeting their basic physical needs (e.g., shelter, safety, nutrition,

clothing) to those considered important to achieving the family's own goals (e.g., healthy physical and social environments in the community, availability of affordable and high-quality child care and public education, adequate employment opportunities currently and in the foreseeable future, good-quality and accessible health care and prevention services) and desirable for promoting maximal well-being (e.g., strong social networks, cultural and recreational opportunities, opportunities to become engaged in the local and larger communities).

Another high source of stress to a family is whether the social unit itself will continue—that is, whether the parents will stay together and whether and under what circumstances their children will continue to live with them. The reasons for disruptions to family units and membership are many, including divorce or the end of a collaborative parental relationship, serious mental health problems in one or both parents, and legal situations that take a parent or child away from the family unit. Such major disruptions almost always comprise a serious stressor that necessitates many changes for the family in its daily life and the availability of resources (social, financial, physical) to rear young children.

Stressors to a family often are dichotomized into those originating primarily within the family unit (intrafamilial) and outside (extrafamilial). Regardless of origin, major stressors to the family can spread and escalate when not abated by effective resiliency strategies or supported by resiliency resources. An extensive body of research documents the negative effects of chronic exposure to high levels of stress on the physical health and longevity of individuals, accounting for many of the entrenched health disparities observed between high- and low-income families and between majority and minority ethnic and racial groups. Increasing scientific inquiry explores the ways in which family stress and resilience can contribute to (a) the integrity and functioning of the family as a unit and (b) young children's outcomes in terms of health, cognition, brain development, social and emotional development, and school readiness and

later school and work success. This line of inquiry now even extends as early as the preconception and the prenatal periods.

Applying Research Findings to Programs and Services for Families

Many fluctuations and transitions in family life can be considered normative and fairly predictable, while others are far less so. Thus, with a longitudinal lens in place, there are many practical implications of the biosocial systems principles that characterize family units. Biosocial systems principles inherently work to promote families achieving homeostasis—a healthy balanced system of functioning. For families, however, what homeostasis “looks like” is far from a simple, static, or universal picture. This leads to the proposal that “family homeostasis” represents a delicate and frequently changing state in which the roles and behavior of individual family members, subunits within the family, and the family as a whole accommodate the demands on the family adjusted to their resources to achieve positive outcomes for individuals and the family as a whole, without violating major societal norms and expectations.

These systems principles can help service providers and educators to identify strategies that can promote, but will not always guarantee, a balanced family system. Under times of duress and particularly when adjusting to unexpected major fluctuations, the family's early responses can be viewed as more (or less) resilient—that is, successful in minimizing (versus not lowering or even increasing) harm from stressors to the family and individual family members. Careful observation of and discussion about these early responses can form the basis for evidence-informed interventions and supports for families during times of heightened vulnerability.

John G. Borkowski, Sharon Landesman Ramey, and Marie Bristol-Power led a National Institutes of Health (NIH) conference forum that built consensus among developmental scientists about the research evidence about the most important ways that parents promote their young

children's development. Briefly, the acronym RPM3, representing Responsive care, Prevention and protection, and Monitoring, Mentoring, and Modeling, captures the consensus summary. These parent activities all fall within the construct of resilience strategies and promoting childhood resilience. The practice of RPM3 simultaneously confers benefits to children and provides a robust biosocial systems framework that helps families to maintain equilibrium (or homeostasis) during periods of transition and duress.

Applied developmental science has engaged in conducting multiple experimental interventions to help children overcome the negative consequences of intergenerational family poverty and accompanying chronic stressors. These studies provide a rigorous test of the hypothesis that human development is malleable, rather than largely predetermined by circumstances of birth and inheritance. Many intervention studies sought to change parenting knowledge and practices and many directly supplemented the family's resources by providing early, high-quality, and continuous care and educational programs for their children. Collectively, these interventions have sought to increase effective family resilience strategies while also decreasing stressors. The findings from these early family and child intervention studies often demonstrate that both the children and parents benefit, with short-term benefits forming the mediating path to longer term benefits. The highly effective interventions have essentially delivered what is captured in the NIH RPM3 summary (see above). They offer multiple opportunities for parents to learn more about child development, effective (versus ineffective) ways to teach and play with their children, and how to anticipate and solve problems in their own lives that they self-identify. In addition, these interventions often provide the extrafamilial supports and direct educational opportunities for children that some families cannot realistically provide completely on their own. The enduring benefits of these interventions potentially can disrupt intergenerational patterns of dysfunction, poor health, and undue exposure to chronic stress with insufficient resiliency resources.

Conclusion

Achieving family resilience is a highly desirable goal that results in benefits to each family member and to the family unit as a whole. Resilience requires learning and flexibility because it is a changing characteristic of a complex and developing system. The scientific evidence is strong that aspects of family resilience can be learned and that a wide array of different resilience strategies can ameliorate negative effects of high levels of family stress on child outcomes.

STUDENT TEACHING

See Internships; Student Teaching and Internships, Issues in

STUDENT TEACHING AND INTERNSHIPS, ISSUES IN

The field of early childhood education is inclusive of a variety of professional roles, but primarily consists of those who teach young learners in educational settings. Preparation of those teachers is of paramount importance since their classroom practices will potentially have a significant impact on very young children; indeed, children's earliest educational experiences may even set the trajectory for future performance in school. Undoubtedly, then, the preparation of early childhood educators should be guided by reliable, professional knowledge of evidence-based practices. One such practice, critically important to the development and learning of future teachers for young children, is the provision of quality clinical experience. In this entry, early childhood education student teaching and internships are addressed. The terms *student teaching* and *internships* are used here as included in the broader terminology, *field experiences* and *clinical experiences*.

Clinical Experiences

Clinical field experience is understood to be a strong component of preparation and induction into the teaching profession. Prior to moving into the role of early childhood educators, novice teachers will have accumulated varying numbers

of internship hours as part of their educational preparation. The National Association for the Education of Young Children (NAEYC) has articulated specific expectations regarding clinical experiences for those who will work with children from birth to age 8 and their families, including student teaching and other field-based internships. Specifically, NAEYC requires that early childhood teacher candidates have field experiences in at least two different early education settings, which can include child care centers, homes, Head Start agencies, primary schools, and elementary schools. Additionally it is required that candidates participate in fieldwork with at least two different early childhood age groups; this includes birth to 3 years of age, 3 to 5 years of age, and 5 to 8 years of age (NAEYC, 2010).

History

Historically, preparation for early childhood educators consisted primarily of an apprenticeship approach. Those who aspired to teach kindergarten in the late 19th century, for example, were typically trained under master teachers, acquiring the skills needed to become effective educators through observation and gradually increasing participation in classroom teaching. This practical approach to teacher preparation, with little time for the study of theory, was necessary to meet the growing demand for caregivers and teachers outside of the family.

During the late 19th and early 20th centuries, the system for preparing early childhood teachers included an increasing emphasis on theoretical coursework, but maintained a practical focus as well. Even as normal schools and other training schools began to include programs for teachers of young children, the practical experience component of the education for early childhood teachers remained. In many cases, kindergarten teachers were placed in classrooms at the time they entered training programs (Thompson, 1992). While this placement system was primarily a response to the demand for teachers of young children, the candidates' authentic experiences with children very likely allowed the coursework to inform their practice and vice versa. Thus, although programs

have been characterized by shifts in focus throughout the years, practical experiences have consistently been included as a valued component of early childhood teacher preparation.

Trends and Variance

Authentic clinical experience is highly valued as an essential factor in all teacher preparation programs. A 2011 report from the National Council on Teacher Quality critiqued teacher preparation programs, emphasizing a need for a greater focus on high-quality, field-based experiences. While the public cry for the inclusion of quality clinical experiences is recent, the emphasis on clinical experiences of those who will teach the youngest learners has always been present. Such field experiences may include internships, practicums, and student teaching participation, with preservice teachers placed under the supervision of expert mentors. This clinical focus is considered by many within the profession to be a mainstay of quality preparation for future early childhood practitioners. Many early childhood professionals would assert that in order to become effective teachers of young children, candidates benefit from multiple, authentic classroom experiences; the knowledge and skills needed to interact with children in a manner that is most supportive of their total development and learning would be best acquired in the context of real classrooms with real children.

If authentic classroom experience with children is understood as essential in early childhood teacher preparation, it is also clear that the specific configuration for programs can be significantly varied. The types of placements, the number of clinical hours required, and the levels of candidate involvement can deviate greatly from program to program. For example, in one, centrally located U.S. state, the requirement for field experience is a minimum of 45 hours of diverse field experience, or its equivalent, prior to the student teaching experience. Additionally, a minimum of a 12-week, capstone internship, a full-time student teaching semester, must be completed by all early childhood teacher education candidates, prior to program

completion and recommendation for licensure. In that state, placements must include a split block student teaching experience, with 8 weeks spent in a pre-k or kindergarten classroom, and the remaining 8 weeks spent in a first-, second-, or third-grade classroom. Beyond that requirement, which is necessary in order to meet NAEYC accreditation guidelines, clinical experiences vary greatly from program to program. There may be a series of internships that lead to student teaching, organized as a gradual release approach to increasing candidate experiences; conversely, there may be very few required field experiences prior to student teaching. Furthermore, the required assignments in each of those settings may vary from observation only, to menial tasks such as making copies or grading papers, to participation in the full range of early childhood teacher responsibilities. The variance in this state is certainly not unique, and similar differences, from program to program, would likely be characteristic of early childhood teacher preparation programs across the United States.

The variance found in U.S. programs appears to be common to field-based early childhood experiences from a more global perspective as well. While certain features of clinical experiences might be more prominent within a particular country or region, differences do exist from program to program, with regard to placements, as well as other requirements for future early childhood teachers. In other words, while national and regional recommendations or general policies may exist with regard to clinical field experiences, there is not a universal approach or set of guidelines for student teaching and internships within the field of early childhood education.

Potential Outcomes of Clinical Experience

Differences within and across countries, regions, and states are potentially a very positive reality, on the one hand; unique features of field experiences for future teachers of young children suggest that programs maintain an important level of autonomy in their preparation programs for early childhood educators. Teacher preparation professionals,

trusted to create meaningful internship experiences for their candidates that are compatible with their overall preservice programs, are empowered to craft the kinds of clinical experiences that would be considered high quality. Such experiences are certainly more likely to result in well-prepared, competent novice teachers for young children, a common goal for all early childhood teacher preparation programs.

On the other hand, variance in field experience requirements from program to program may also be viewed as a potential detriment to quality within the early childhood workforce. For example, with no common standard in terms of hours required, or specific expectations for clinical experiences, there exists the possibility that some future teachers of young children may complete programs of study having had very little authentic experience with children in classrooms. Additionally, while some candidates may have an adequate number of field hours, the bulk of those hours may be spent observing another teacher; while observation of exemplary teachers is a necessary and valuable experience for future early childhood teachers, it falls short of fulfilling the goal of meaningful field experiences. In other words, if little or no time is spent interacting with children, planning and implementing curricula, or documenting and analyzing children's development and learning, candidates have had no opportunities to develop and refine the skills needed to become effective, high-quality teachers of young children.

As previously stated, NAEYC provides guidance regarding clinical experiences for those who are preparing to become teachers of young children. All institutions whose early childhood education programs lead to teacher certification, and which are accredited through the Council for the Accreditation of Educator Preparation (CAEP), must provide data to demonstrate their effectiveness in the area of field experiences. In order to meet accreditation requirements, an institution must document high-quality field experiences regarding the types of placements included in candidate clinical experiences, as well as the ages of children with whom candidates are placed. Those

general guidelines are supportive of quality and certainly indicate the potential for excellence in early childhood education clinical experience. Still, it is the responsibility of each preparation program to create a series of authentic, robust field experiences; such opportunities, much like the early apprenticeship approach, can lead early childhood teachers to become skilled in the art and craft of supporting young children's learning and development under the supervision and mentorship of expert practitioners.

Conflict

One problematic issue, often discussed among those who prepare early childhood teachers as well as student teachers themselves, is the mismatch that candidates may find between what they understand to be best practices for young children and what they experience in many classrooms. Particularly in public school settings that are held accountable by state and federal policies, early childhood student teachers may experience feelings of inner conflict as they attempt to put into practice what they have learned in college courses. For example, candidates may be expected to teach young children through the use of worksheets, primarily in a whole-group structure, from a predetermined curriculum. This is in stark contrast to teaching practices that support young children's ability to learn best through active, authentic engagement with content that is individually and culturally relevant to children in classrooms. For the early childhood teacher-in-training, who has limited experience and is yet to have full decision-making ability, the internship experiences may range from mildly stressful to extremely intolerable.

Clinical Experiences = Authentic Learning

As a result of the coursework-to-classroom discrepancy, one might speculate that field-based experiences, designed to promote and solidify candidates' skills and abilities as early childhood teachers, may actually impede their opportunities to demonstrate excellence. However, many

candidates maintain their commitment to best teaching practices for young children, whether or not their clinical experiences provide consistent models. Indeed, a great many early childhood educators move into their first teaching assignments with the knowledge, ability, and conviction to provide outstanding, child-centered learning opportunities for young children. In those cases, one can assume that the internships and student teaching experiences have supported candidate understanding and are effective components of their respective preparation programs.

Involvement in internships, student teaching, and other clinical experiences provides early childhood teacher candidates with invaluable opportunities to learn. In the most positive cases, those experiences take the form of successful tutelage under expert, mentor teachers, with candidates engaged in planning and implementing quality, child-centered curricula. At times, however, those experiences involve learning how to navigate the conflict between theory and practice that too frequently exists when local practices are inconsistent with candidate pedagogical knowledge. Whether or not clinical experiences serve their intended purpose of allowing early childhood teacher candidates to observe and practice in a manner consistent with their growing professional knowledge, it is undeniable that those experiences play an important role in teacher preparation. Apart from the genuine context of young children in classrooms, future early childhood educators are lacking the most critical preparation of all: the actual practice of the art and craft of teaching. In order to develop the knowledge, skills, and dispositions necessary to fully support young children as learners—as whole human beings—early childhood teacher candidates must have opportunities to practice, with support from mentors and supervisors, all aspects of what it means to be a teacher.

SUBSTANCE ABUSE AND ADDICTION

Three areas are key when considering substance abuse in the context of early childhood. These are the impact of exposure to drugs of abuse during the prenatal periods, the impact of parental substance use on parenting and a child's environment, and the predictive factors from early childhood to the initiation of drug use in early adolescence.

Regarding maternal substance abuse and addiction during pregnancy, the fetus and infant are at risk because of the direct teratogenic effects of exposure to potentially neurotoxic drugs at key times in gestation, the exposure to maternal chronic stress and poor health that often accompany substance abuse during pregnancy, and the overall greater comorbidity with other psychiatric

disorders. In turn, psychiatric disorders such as chronic depression and anxiety potentially convey heightened genetic vulnerability to the fetus, impact an adult's ability to care for his or her child, and are associated with other contextual factors including joblessness, poor education, homelessness, greater risk for involvement with the criminal justice system, and overall greater risk for early involvement of child protective services. Parsing out each of these contributions to the long-term impact of maternal substance abuse is key to a more detailed and nuanced understanding of prenatal drug exposure though each is highly correlative with the others.

The fundamental logic for questions of prenatal drug exposure is whether exposure to a drug (or disruption of a developmental process because of the mechanism of action of the drug) during a specific phase of development causes a given outcome or outcomes immediately or later in development. One drug may produce several different outcomes depending on the amount and timing of the exposure, and there may be different dose-response curves for the different outcomes, that is, some developmental effects occur at lower exposures than others. Neurobehavioral changes may occur at lower doses than abnormal growth or disrupted organogenesis. There may also be varying dose-effect models; these can include a directly linear model, in which cumulative exposure results in increasingly worse outcomes, as well as a threshold model, under which only exposure above a certain threshold results in adverse outcomes. Further, many neurodevelopmental outcomes are not evident immediately in the newborn or early infancy but are only apparent across development as, for example, cognitive demands increase (e.g., the need to focus attention in school). Or adverse neurodevelopmental outcomes or vulnerabilities may only be apparent under stressful or depriving postnatal environmental conditions but are not evident under average, expectable caring environments.

Most, if not all, of the questions regarding prenatal exposures to drugs of abuse involve the more complex developmental models of exposure. For one, rarely are the exposures to a single drug. For

example, cocaine users typically also use other drugs including alcohol and tobacco. Secondly, rarely do drugs of abuse, even with heavy exposure, uniformly result in clear adverse outcomes, and the severity or extent of the developmental effect is variable. For instance, prenatal exposure to alcohol, sometimes even at high levels, does not consistently result in fetal alcohol syndrome. Thus, understanding the effects of prenatal exposures to drugs of abuse requires taking into account more complex exposure models and mechanisms including interactions between the drug exposure and the environment. That is, does the environment in one way or another moderate the fetus's risk of exposure as well as vulnerability to the potentially toxic effects of the exposure? For example, is prenatal cocaine exposure more toxic because of the often-associated poor maternal nutrition and/or poor access to health care? The drug-using environment may also determine other risk factors that mediate the severity of any exposure-related outcome. For instance, maternal depression and/or posttraumatic stress disorder are often associated with maternal addiction and in turn may impact the ability of a mother to care adequately for her newborn.

Genetic factors are also key, for it may be that the same underlying genetic profile that may increase the risk for abusing potentially addictive drugs conveys risks for other psychopathology (e.g., depression, anxiety) as well as transmits that same genetic risk to the fetus. Further, these same genetic factors may be more susceptible to the epigenetic effects of stressful environments. Indeed, many view addiction as a stress disorder and the result of impaired stress-regulatory neural mechanisms. In this perspective, what may be toxic about direct exposures to drugs of abuse is how that exposure impacts the emerging stress-regulatory systems in the fetus as well as the fetal exposure to the dysregulated maternal stress response system. Indeed, chronic prenatal stress in mothers results in changes to maternal stress and immune systems that may have direct effects on similar systems in the fetus. A growing body of human research also indicates the deleterious effects of

prenatal stress on birth outcomes and postnatal development.

With these caveats in mind, there are a few important generalizations regarding the overall neurotoxic effects of the most common drugs of abuse. There is a spectrum of disorders related to prenatal alcohol exposure ranging from fetal alcohol syndrome (fully or partially expressed) to so-called alcohol-related neurodevelopmental disorder and alcohol-related birth defects with associated cognitive impairments in varying degrees. Although less clear, prenatal marijuana exposure in humans may be associated with deficits in language, attention, and cognitive abilities. Prenatal opiate exposure is associated not only with neonatal withdrawal; children exposed to a prenatal opiate such as heroin also tend to perform worse on general cognitive tasks, including those associated with memory. Prenatal tobacco exposure is associated with lower birthweight and a potentially increased risk for conduct disorders in early childhood.

Drugs acting as potential neurotoxins during pregnancy may do so through mechanisms similar to those through which they exert their psychoactive effect for the addicted adult and hence it is important to understand their mechanisms of action relative to the timing of the exposure and the neurodevelopmental processes most active during that time. Prenatal cocaine exposure provides an illustrative model. Cocaine acts at the level of the synapse by blocking the reuptake and metabolism of the monoaminergic neurotransmitters dopamine, serotonin, and norepinephrine. In the adult, slower reuptake results in more stimulation of the postsynaptic neuron and hence, the neuroexcitatory properties of cocaine. But in the developing brain, monoamines exert a trophic effect on brain growth and neural differentiation and thus, changing the metabolism of monoamines at the level of the developing neuron may also impact neuronal growth and functioning. For example, in the nonhuman primate, cocaine impacts cortical differentiation and layering with the resultant disruption of the usual orderly layering of cortical neurons. Impacting the growth and

function early on of monoaminergic neurons may also directly impact monoaminergically regulated neuronal systems such as reward sensitivity and adaptive stress reactivity. Indeed, both of these outcomes are seen in animal models exposed to cocaine prenatally. The long-term effects of cocaine in humans is less clear with studies marked by a host of confounding factors including polydrug exposure and psychiatric comorbidity. That said, it appears that prenatal cocaine exposure may convey across development a greater vulnerability to the detrimental effects of chronic stress and greater difficulty in emotion regulation with the attendant increase in risk for mood-related psychiatric disorders by adolescence and young adulthood.

Central to the question of prenatal exposure is the postnatal environment that infants exposed to substances prenatally often continue to live in. In this regard, understanding how addiction impacts an adult's capacity to parent a child is key. Less important in this instance are the specific drugs of abuse—though each certainly has different neuropsychological effects in the adult—but more the effect of an addictive process on cognition, attention and reward mechanisms, and stress regulation. Key here is the definition of addiction of which substance or drug abuse is one example. Addiction is a state characterized by compulsive engagement in seeking rewarding stimuli despite adverse consequences. The stimuli are reinforcing, that is, they increase the likelihood that an individual will seek repeated exposure to them and they are intrinsically rewarding, that is, they are desirable. While a number of stimuli may initially be primarily positively reinforcing, many, if not all, addictive situations involve negative reinforcement, that is, the reward is in the reduction or avoidance of negative/stressful emotions. In other words, commonly, in the addictive situation or process, the relief of stress afforded by the drug leads to habitual drug use, and the reward system is “co-opted” to maintain habitual behavior linked to relief of stress or avoiding negative emotions. With this co-optation, other more adaptive rewards are not as salient for they are not part of the conditioned stress relief–reward link. Importantly, as

Helena Rutherford and colleagues have suggested, these more adaptive rewards include social affiliation and relationships, and this kind of co-optation has profound implications for parenting behaviors among addicted adults.

Parenting involves a special adaptation of both reward- and stress-regulatory neural systems to the relevant cues from offspring that become highly salient for the adult, now a parent. But for the addicted parent, the addiction process itself may impair those same neural circuits required for attention and response to the infant and the salient cues underlying caregiving. Indeed, while parenting behaviors vary considerably among addicted adults, there is a greater incidence of abuse and neglect of the infant and a tendency to withdraw from the infant's crying and distress, each potential markers of the adult's withdrawal from stressful situations and contexts. Further, addicted adults more commonly have histories of their own early abuse and neglect that increases their risk both for addiction and other comorbid psychopathologies as well as for repeating the abuse and neglect in their parenting role. They also more commonly suffer from depression and anxiety as comorbid conditions, thus increasing the stress and burden of the caregiving role.

The combination of greater vulnerability conveyed through both prenatal exposure and the postnatal caregiving environment sets the stage for increased risk across development for problems with stress regulation as well as impulse control and attention allocation and learning. As cognitive and developmental demands increase, these vulnerabilities may become more apparent. This is especially true in adolescence, a time of great neurodevelopmental reorganization and neuromaturation. Of great concern is the possible developmental line between both intrauterine and environmental exposure to drugs, the addictive environment, and the initiation of drug use in adolescence. Adolescence marks an important developmental period with heightened vulnerability to substance use and higher rates of dependency and substance use disorders during this developmental period when compared with adulthood. Further, the

earlier onset of substance use in adolescence predicts greater addiction severity in adulthood and greater comorbidity with other psychiatric disorders. Central to understanding the risk for substance use and abuse in adolescence is an apparent development paradox that contrasts the near-adult-level maturity of executive and decision-making functions with heightened risk-taking behavior even with prior knowledge of the consequences of this behavior. In adolescence, the cognitive control system, including prefrontal and parietal regions and the anterior cingulate, is crucial to decision making but is functionally dominated by a second affective system that includes regions that are important to processing reward and social and emotional salience, including, but not limited to, the amygdala, ventral striatum, orbitofrontal cortex, medial prefrontal cortex, and superior temporal sulcus. The dominance of the affective system contributes to heightened reward sensitivity and a reward-seeking behavior, a crucial factor biasing decision making and contributing to increased experimentation with drugs and the emergence of substance use and abuse. Further, the long-term effects of exposure to drugs and chronic stress prenatally and to an addictive, postnatal caregiving environment contribute through a host of mechanisms including epigenetic ones to a more vulnerable stress-regulatory system in adolescence. When heightened reward-sensitivity and reward-seeking behavior are coupled with this long-term developmental effect on stress-regulation during adolescence, those youth are more likely than their nonexposed peers to seek out drugs and to convert from use to abuse. In this way, prenatal drug exposure with the attendant postnatal effects through the caregiving environment have a two- and three-generation effect on the likelihood of substance use and abuse. This complex intergenerational transmission mechanism may inform the often-observed multigenerational history of substance abuse and addiction in families. Further, understanding the mechanisms for the potential intergenerational transmission of vulnerability to addiction points to intervention models that focus more on family health, stress management, and

attending to the parenting capacities of substance abusing mothers and fathers.

TEACHER BELIEFS

Teaching is complex and teacher practice is influenced by teacher knowledge, beliefs, and experiences, children's characteristics, administrative and parental expectations, and resources available. This entry provides information on teacher beliefs: how beliefs influence behavior, sources of beliefs, and how beliefs are formed and changed. The focus of this entry is on two distinct belief strands: (1) teacher beliefs about the nature of learning and teaching and (2) teacher beliefs about their own abilities.

Overview

Teacher beliefs are major determinates of classroom practice. Beliefs differ from knowledge in that knowledge is based on objective facts or evidence whereas beliefs are based on affect, subjective evaluation, and judgment. Beliefs are referred to as attitudes, feelings, values, or dispositions. Beliefs influence teacher perceptions, judgments, and decisions every day. In early childhood education, beliefs encompass caregiving, parenting, and teaching. The variation of beliefs is great because everyone has experienced being a child and a student and most have been raised in a family. When courses about child development, subject matter methods, or family involvement are introduced, prospective teachers already have experiences and core beliefs about those topics. The strength of

these core beliefs of course participants will impact the effectiveness of any formal educational effort.

Beliefs About the Nature of Learning and Teaching

Teacher beliefs about the nature of learning and teaching influence classroom decisions and teacher behavior toward children, family members, and administrators. The interactions in the classroom are multifaceted, and there are a high number of ongoing decisions that have to be made when expectations are vague, ambiguous, or conflicting. Beliefs guide the decisions when practice is unclear. In early childhood, teacher beliefs and practices fall along a continuum of philosophical principles from learner centered to teacher directed. For instance, the curriculum the teacher selects is partly guided by teacher (or administrator) beliefs. If the teacher believes that children learn best by constructing their own knowledge (learner centered), then teachers will offer inquiry experiences, small groups, and opportunities for peer interactions. The classroom will be arranged in centers with lots of objects and resources available for children to explore. Teachers will provide a curriculum framework of projects or themes based on children's interests. Teachers will interact with the children individually, in small groups, or, when appropriate, in larger groups.

If the teacher believes children learn best by listening to and learning from adults (teacher directed) or other sources, then teachers will offer lots of large

group experiences and very little child choice in the classroom. The curriculum framework provided would be scripted curriculum or teacher-directed curriculum units.

If a teacher believes that family members care and can contribute to their child's education, that teacher will more likely welcome family participation and involvement. If a teacher believes that family members cannot be partners in their child's education, that teacher will not offer opportunities for families to become involved in the classroom activities. Although many other factors contribute to these practices, the level of effort, affect, and motivation teachers feel will come from teacher beliefs.

Teacher Beliefs About Their Own Abilities

Albert Bandura's self-efficacy theory describes how teachers are influenced by how they feel, think, behave, and motivate themselves. Self-efficacy beliefs are not skills but the belief of what one can do with those skills. Self-efficacy beliefs are actually better predictors of behavior than actual capabilities. Even if one has the skills and knowledge, if she does not believe she can be successful, chances are she will not succeed. Self-efficacy beliefs are situation specific. The strength of a self-efficacy belief helps determine how much effort teachers will expend on an activity, how long teachers will persevere when confronted with obstacles, and how resilient teachers will be when faced with adversity. For instance, a teacher may be conducting a science experience with young children. If the teacher feels or believes he can carry out the activity, that is, understands the science concepts (high self-efficacy), he will be successful, or if he is doubtful, he will tell the children that they need to look up the answer together. If the teacher feels or believes he does not like science (low self-efficacy) or he believes he does not understand the concepts, he may skip the activity or present it without conviction or enthusiasm.

Teacher effectiveness will vary from one task to another. Teachers ask themselves questions every day, all day long about being successful with all children, managing the classroom, and helping children learn. A strong sense of efficacy fosters a

high level of enthusiasm, learning, and development of intrinsic interest in learning. Some of the major research specifically related to self-efficacy and teaching include the following outcomes:

- Teachers with a high sense of instructional efficacy believe that all children can learn and use a variety of strategies to ensure that all children learn. When setting goals, teachers work with students, making joint decision making and learning the primary focus.
- Teachers with a high sense of teaching efficacy take personal responsibility for student learning.
- Teachers with high self-efficacy have an openness to student ideas and feelings whereas teachers with low instructional efficacy have more of a custodial orientation, present a more skill-based curriculum, control through strict regulations, and have a negative view toward challenging behavior.
- Teachers with high personal and professional self-efficacy feel good about themselves and believe teaching can make a difference in the lives of children.

The early years are a formative time for young children to develop their own conceptions of their capabilities. Children learn about their capabilities through social construction with adults, peers, and experiences. When activities are challenging but matched to the children's abilities and young children are successful, they will form a positive perception of their ability to learn. Early childhood teachers' sense of efficacy is likely to be especially influential since young children are still forming their beliefs about their capabilities. Teacher beliefs are central to the socialization process and help set a climate for learning.

Sources of Beliefs

Many factors influence beliefs, including the teacher's prior experiences and education, classroom and school contexts, and mandates. Personal and professional experiences are a main source of beliefs. Family experiences and upbringing will be a fundamental source of how one believes people

are treated and how one interacts with others. M. Frank Pajares has commented on the fact that prospective teachers in teacher education programs believe they know how to be a teacher because they have been in a classroom for 12 years. Professional experiences via practicums and student teaching offer examples for novice teachers to form, question, or reinforce beliefs. Formal professional opportunities influence belief systems by exposing prospective teachers to new ideas and knowledge. Efficacy beliefs are enabled by providing opportunities to learn skills to make teachers feel more confident.

Situational contexts will impact beliefs. If a teacher feels comfortable about a situation, she will be more successful, for instance, if she has the knowledge to accomplish a task that is necessary but not sufficient for competent performance. The teacher must also feel or believe she has the ability to organize and execute the task. People behave according to the context or situation, and the degree of similarity to other successful experiences will increase the likelihood of accomplishment.

Bandura has presented four sources of self-efficacy beliefs: (1) successful experiences, (2) vicarious but successful experiences, (3) verbal persuasion, and (4) enhanced physical status. When designing experiences for a prospective teacher, the best way to enhance self-efficacy beliefs is to provide for successful experiences. When a prospective teacher can see the impact of helping children learn a concept or skill, he will more likely believe in his ability as a teacher. When a prospective teacher can see successful implementation of strategies and the impact of learning through vicarious experiences, there is also a possibility of the teacher feeling that he too can accomplish that task. The closer the experience the prospective teacher views to what he has to do will also increase the likelihood of higher self-efficacy and successful completion of a task. Verbal encouragement that she can accomplish a task from significant others has the likelihood of increasing self-efficacy beliefs. And last, reducing stress levels and recalling past successes will enhance a prospective teacher's physical states so he can feel like he can accomplish a task.

Changing or Guiding Beliefs

Teacher educators and administrators may want to know how to influence prospective or current teachers' beliefs. Beliefs and belief systems are difficult to change or alter. Since beliefs are constructed through experiences, some are formed early and are resistant to change or modification. Measuring the strength or intensity of the belief before any effort is made to alter it will provide valuable information. Sometimes one can tell what people believe by their practice or by a survey. The relationship between beliefs and practice is one that is worthy of exploring in teacher education programs.

Here are some steps to follow when providing for teacher education or professional development experiences. First, try to have participants reflect on current beliefs. Articulate and examine beliefs through whole-group discussions, case studies, journaling, simulations, and small-group reflections. Pajares has stated that unexamined beliefs perpetuate the status quo and many times ineffective practice. Second, link beliefs to practice. If teachers believe that all children can learn, discuss what that will look like in the classroom. Verbalize the practices that will represent this belief. Once the teacher can operationalize the belief, then examine the practice and determine to what extent the interaction or strategy is successful. Change is more likely to occur in experiences where teacher and prospective teacher listen, reflect, and learn from one another.

Next, increase the knowledge base and skills. Increasing the knowledge base and skills will lessen prospective teacher self-doubts and sense of vulnerability. Vicariously present through video the practices that are most effective while discussing why the practice is the most effective strategy. Technology has enabled the use of videos to demonstrate effective practice in classes on campus. Observing or providing opportunities for real experiences are even more powerful. Reflecting on experiences can provide the difference that could alter a belief.

Self-affirming experiences will help enhance beliefs. When prospective teachers can actually

see practices that were discussed in methods courses, beliefs will be enhanced. When prospective teachers can be placed in classrooms where they can implement course ideas, then teacher education program philosophic strategies will be reinforced.

Last, if prospective teachers have progressive beliefs that are aligned with effective practices, those beliefs need to be acknowledged and supported. Those progressive beliefs need to be at the core of the prospective teacher's belief system.

TEACHER EDUCATION

See Early Childhood Teacher Education; Preservice Teacher Preparation

TEACHER MATERIALS FOR DOCUMENTATION

In the field of early childhood education, the term *documentation* is used in two ways. First, documentation is the act of collecting and sharing evidence of growth in children's knowledge, skills, and/or dispositions (i.e., documenting children's learning). Second, the materials that are shared as evidence also are referred to as documentation. This entry examines documentation practices and strategies for effective documentation. It further outlines why documentation is an effective way to collect evidence of children's development over time, the importance of displaying documentation, and best practices in documentation.

Documentation: An Active Process

Documentation is particularly useful in assessing the growth and development of young children's knowledge and skills since it is more reliable than standardized assessments for children 8 and under. In addition, documentation allows teachers to assess changes in dispositions or inclinations of temperament (e.g., persistence, impulsiveness, curiosity). Evidence of children's growth is typically collected over time and provides a picture of a child's ongoing development, as opposed to a snapshot of one moment in time provided by standardized assessments. Documentation also allows teachers to examine and share the progress of children whose performance may appear delayed when compared with that of other children (e.g., children with special needs, dual-language learners, children from low socioeconomic backgrounds).

While a learning experience may produce the same outcome for multiple children, each of the children may reach that outcome via a different pathway. Documenting children's learning over the course of an emergent learning experience may help a teacher gain insight into *how* individual children reach an outcome. The teacher can then use that insight to develop more effective strategies for individualizing instruction. She may also develop insights

into the experience and growth of the group as a whole, and can use these insights to improve the responsiveness of her overall instruction.

Documenting children's learning can also help a teacher in communicating the value of her method or approach to teaching to families and others whose approval that teacher might seek. For example, teachers who provide emergent learning experiences that are responsive to the interests and abilities of the individual children in the class, such as the project approach, may document for purposes of accountability. By documenting emergent learning experiences teachers may demonstrate that children in their classes are meeting learning standards, and they can track the meaningful process through which the standards are being met.

Documenting children's learning also supports the ability of teachers to reflect on the content and quality of their own teaching and to share their experiences with other educators. As teachers engage in collecting, selecting, and preparing documentation of children's individual and group learning experiences, they may become more aware of strategies or experiences that worked well or those that needed revision. Documenting then becomes a kind of professional development activity, as a teacher studies her own teaching. Documenting children's learning also can contribute to a teacher's professional development when it is used as a basis for discussion with other teachers. Teachers can use their documentation as a context for discussing the merits of teaching practices and experiences with colleagues.

Strategies for Documentation

Teachers use a variety of strategies to document children's learning. When teachers are aware of developmental pathways across domains of learning, they can use active observation to identify the progress of individual children or the group as a whole. Teachers can collect data by observing and collecting samples of what children make, say, and do. Samples might represent the process a child or children go through as they use materials in the environment to help them think about something

or develop a new skill or disposition. They may be collected at various points in the process of learning about something. In other words, they are not necessarily the final product of a learning experience.

Examples of what individual children make might include drawings, three-dimensional constructions, block constructions, or writing samples, while examples of what groups of children make might include group murals or group three-dimensional models or constructions. Examples of what individual children say (e.g., "My grandma told me I'm a good drawer, and it's true!") might be captured with anecdotal notes, or with audio or video recordings of children's statements, while examples of what groups of children say might be captured with a web, list, or book in which multiple children have contributed ideas and illustrations. Examples of what individual children do (e.g., engaging in complex play representing the activities of a pizza parlor manager) might be recorded through anecdotal notes, photos, or video. In addition, some behaviors can be documented by tracking their frequency, duration, or location within the classroom on a matrix or other specially prepared form. Developmental checklists, such as Teaching Strategies GOLD, the Child Observation Record, or the Work Sampling System help teachers to monitor growth in children's abilities.

Documentation: Evidence of Children's Growth Over Time

The term *documentation* also refers to the evidence of the children's work that the teacher has collected (e.g., anecdotal notes, audio recording, work samples) and to the picture of the process of learning and development of individual children or groups of children created over time through a display of their work. Thoughtful display of the evidence can effectively create a picture of the learning experience and growth in knowledge, skills, or dispositions of an individual child or a group of children.

The combination of multiple samples is a useful strategy for demonstrating growth. For example, a teacher might jot down a record of what a child says as she draws a picture of a car. The child's

comments might reflect an understanding that tires have letters and words on them (e.g., the child says, “ATA, that’s the plane I rode on,” as she writes the letters A, T, and A on one of the tires in her picture of a car). Displaying this statement in combination with the child’s drawing of a car, plus a photographic image of a real tire, would be more powerful evidence of the child’s understanding than displaying the child’s statement in isolation.

Teachers in U.S. schools and child care centers typically send children’s work home once it is completed. However, teachers who save samples of children’s work over time are better able to document growth. For example, at the beginning of a project on butterflies, a child might draw a butterfly as a body with two triangle wings and a smiling face. However, after six weeks of investigation, the child’s drawing might include four wings with scales, three body segments, antennae, and a proboscis. Displaying the two drawings side-by-side creates a picture of the growth in the child’s knowledge about butterflies. If the teacher had not saved the first (Time 1) drawing, she would not have the solid evidence of growth in knowledge and understanding depicted by displaying the Time 1 and Time 2 drawings together.

Displaying Documentation

Teachers of young children typically display young children’s work on a bulletin board in the classroom or hallway. Often, every child’s product from a class art activity is on display. Lines of cut-and-paste art projects are stapled to cork strips that line the school hallways. However, by combining sample products of various activities that have taken place during a long-term learning experience, such as a project, teachers can effectively tell the story of the process children went through as they engaged in the learning experience.

As teachers prepare displays of documentation it is important for them to consider the potential audience. Depending on where the documentation will be displayed, the audience might include family members, colleagues, children from the teacher’s class, children from other classes, the teacher herself, and/or individuals who make decisions

that affect support for the teacher’s center or school. Depending on the audience, the teacher may need to include more information about the context for the learning experience, and he may decide to include a narrative that frames the learning experience for that audience. Of course, the teacher and the children from the class are almost always a primary audience. As they select and prepare documentation for display, and as they view the display, teachers deepen their understanding of their individual students’ learning and on their role as the teacher in the learning experience. Children reflect on what and how they have learned.

Teachers who document project work often have a specific bulletin board or area where they display samples of children’s work that is used as a collection point for documentation of the events in the life of the project. This board serves as a sort of diary in which children and teachers record the history of the project (i.e., a project history board). Teachers can take advantage of the potential of this board by including children in the selection of samples of work to be displayed (e.g., “What should we add to our project board that will show what we discovered today?”). This practice helps children learn to appreciate the abilities of others in their class and strengthens the connections among the class community.

When a teacher has a rich, long-term, emergent learning experience developing in his classroom, he may begin to run out of room on the project history board. At that point, he may select samples from the earlier stages of the learning experience and prepare a more formal display for more public areas in the center or school. For example, he might prepare a hallway bulletin board display of children’s work and photographic images with accompanying narrative. In this display, the teacher can help viewers to understand how the project developed, as well as the role individual children played in the learning experience. He can highlight the influence project participation had on growth of children’s knowledge, skills, and dispositions.

Sometimes teachers wish to distill or reduce the size of the documentation display even further. For example, the teacher might want to take documentation of the project to a meeting with colleagues,

display documentation of the project at a meeting of a professional association at the state or national level, or display documentation of the project at the site of the project investigation (e.g., displaying documentation of a project on pizza at the local pizza parlor). In this case, cardboard or foamcore trifold panels, such as those used in science fairs, are often used. Preparing professional-looking trifold displays requires attention to aesthetics and precision in preparing and attaching the samples and narrative.

As computer software has developed and become increasingly user friendly, teachers are able to reduce the time needed to prepare documentation panels and increase the professional appearance of the panels. For example, a teacher can now electronically insert textboxes, images, and scans of children's work. She can size and resize images, move them from place to place, and experiment with fonts and font sizes that increase the power of the documentation in providing evidence of children's learning. Once she is satisfied with her display, the teacher can save it as a PDF file and have it printed as a poster. She can mount the poster for display and conveniently remove it and roll it up for transport or storage. Some teachers also use online, password-protected, user-friendly sites to share documentation of children's learning with children's families. It is important to note that whenever a teacher includes children's images and work, she must have permission from each child's parents or guardian.

While poster and wall displays are discussed here, teachers are encouraged to create other ways to share documentation. For example, some teachers develop binders that document a learning experience. Children can then check the binder out and share it with their family at home. Weekly or biweekly newsletters are an excellent place to document the ongoing development of a learning experience. Some teachers have helped children to develop video presentations in which their students document their own learning. The video is then made available to families on a password-protected site or it is recorded on a CD which is copied for every student's family. Early childhood teachers are encouraged to channel the energy and creativity they formerly expended on "cute" bulletin boards

toward the development of innovative documentation of children's learning.

Strategies for Effective Documentation

Several strategies or rules of thumb can help a teacher prepare an effective panel. First, the less-is-more rule applies here. Potential viewers are less likely to read a documentation panel if it is overcrowded. Balancing empty space with the space taken up by images, samples, and text is important. In addition, grouping items closely together and surrounding them with empty board space sends the message that the items are related. The less-is-more rule also applies to the length of sentences and to the overall length of the narrative. Crafting narrative so that it is succinct but informative increases the likelihood that potential viewers will take the time to read what a teacher has written.

Potential viewers are more likely to be drawn to a panel when it appears lively. However, liveliness should not be equated with loud. Teachers in early childhood education have a tradition of putting up bulletin boards that make use of a variety of primary colors and decorative shapes to draw attention to the board. However, the children's work tends to get lost in the chaos of colors and shapes. Limiting colors used to frame children's work to one color family (e.g., blues, greens, oranges) and avoiding "cute" decorations allow the children's work to stand out. It sends a message to the viewer that the children's work is interesting and worthy of close examination. Another common practice is to display young children's work tilted to the left or right on bulletin boards. Again, this practice sends a message that the children's work is not interesting, since the teacher used it merely as decoration. Teachers can make their displays livelier by developing intriguing titles for their displays, including artifacts and three-dimensional articles in the display, and including quotes from children that reflect their thoughts and feelings about their individual work or participation in the learning experience. It should also be noted that displays in which images are the same size and presented in rows communicate monotony.

Varying the size of images and samples of children's work can contribute to a lively display.

TEACHER PERFORMANCE ASSESSMENT

Teacher performance assessment refers to the evaluation of teaching practices using measures that gather authentic evidence of the day-to-day tasks of teaching. Performance assessment is sometimes used within the context of accountability policy. There is much debate about how to evaluate teaching quality, teacher effectiveness, and accountability for classroom learning. Although many express concerns about an overemphasis on standardized testing as the sole measure of student learning, there is a strong call by

the public to ensure that all teachers are well prepared to meet the learning needs of America's increasingly diverse learners. This entry presents a description of a recent innovation in teacher performance assessment known as edTPA and its use as a measure of teaching effectiveness for early childhood educators.

Overview of edTPA

National organizations like the American Federation of Teachers (AFT) and the Council of Chief State School Officers have asked for a consistent expectation of "readiness to teach" and to ensure that teaching is recognized as a profession along with medicine, law, and so on. As argued by Lee Shulman as the basis of the National Board for Professional Teaching Standards, establishing teaching as a profession requires an agreed-upon knowledge base for effective teaching, and standards of practice that are clearly defined, communicated, and enforced through a certification process. Understanding the important relationship between how children learn and the ways in which teachers are assessed, edTPA follows specific design principles to ensure an assessment focus on student learning through intentional teaching practices and the systematic collection of authentic teaching artifacts. edTPA was developed to provide valid and reliable evidence that newly certified teachers are ready to take on the challenges of classroom teaching from their first day on the job.

Built upon generations of portfolio-based assessments of teachers, including the Early Adolescence/English Language Arts (EA/ELA) assessment from the National Board for Professional Teaching Standards' first assessment development laboratory to assess accomplished teachers, the Interstate Teacher Assessment and Support Consortium (INTASC), the Connecticut Beginning Educator Support and Training (BEST) assessment for early career teachers, and the Performance Assessment for California Teachers (PACT), edTPA is a portfolio-based performance assessment of teaching developed at Stanford University with input from hundreds of educators and university faculty from

across the country. edTPA is currently used by more than 700 teacher preparation programs in 40 states, and teacher candidates in 13 states must complete and pass edTPA as part of their teacher preparation program requirements prior to becoming a licensed teacher.

edTPA Common Architecture

As a performance measure of teaching, candidates completing edTPA plan, teach, and analyze a learning segment of three to five learning experiences taught to a group of P–12 students. Candidates document their teaching using authentic artifacts of practice including context information, plans, video clips, and evidence of student learning. Candidates are continually prompted to consider and evaluate how their understanding of the children in their class has informed their plans, instruction, and assessments.

edTPA is a subject-specific assessment, and each of the 27 versions shares a common three-task architecture (planning, instruction, and assessment). However, each version emphasizes key elements of subject-specific pedagogy based on standards determined by the field and a subject-specific design team. For example, the subject-specific learning emphasis for elementary mathematics requires that candidates support students to demonstrate mathematical practices as they develop procedural fluency, conceptual understanding, and problem solving and reasoning skills. In elementary literacy, for example, teacher candidates support their students to develop an essential literacy strategy for comprehending or composing text, as well as the skills necessary to use that strategy in meaningful contexts. In early childhood, candidates must promote the active and multimodal nature of young children's learning and language and literacy development through interdisciplinary learning experiences. In each of the 27 versions, although the particular content varies, all candidates are expected to support children's learning across three to five experiences and tailor their instruction to reflect their knowledge of students' prior learning, knowledge, and experiences. Candidates

must verify which edTPA handbook to use as determined by an alignment of edTPA handbooks and state credential/licensure areas provided by each state.

edTPA evaluates evidence for 15 constructs associated with effective teaching distributed across the three tasks of the integrated portfolio.

For Task 1: Planning—Candidates demonstrate how their instructional plans build student learning for a subject-specific focus and articulate how those plans meet the strengths and learning needs of their students and how they will plan to monitor student learning across the learning experiences documented.

For Task 2: Instruction—Candidates provide video recordings of their teaching to demonstrate a positive learning environment, how they engage and monitor students in learning, and a key pedagogy approach specific to their field.

For Task 3: Assessment—Candidates analyze student learning through work samples and other evidence, provide and evaluate feedback that supports children's learning, and determine next steps for teaching based on assessment information.

Throughout the three tasks, the candidates explain, justify, or analyze their teaching in reference to their subject-specific teaching and learning focus.

Last, teacher candidates are expected to plan for and to analyze the degree to which their teaching facilitates learners' development and use of academic language in support of deep content learning. edTPA's attention to academic language as the language of the discipline and key language functions (e.g., argue, explain, infer, interpret) is consistent with expectations articulated in the Common Core State Standards for English Language Arts & Literacy in History/Social Studies, Science, and Technical Subjects (Common Core State Standards Initiative, 2010) and intends to leverage teaching practices associated with closing the academic achievement gap for English language learners and all students learning the language of school.

Early Childhood Version of edTPA

edTPA for Early Childhood is consistent with the 2010 NAEYC [National Association for the Education of Young Children] *Standards for Initial and Advanced Early Childhood Professional Preparation Programs* and the National Board for Professional Teaching Standards (NBPTS) *Early Childhood Generalist Standards*. edTPA for Early Childhood also requires that the candidate create a learning segment that includes developmentally appropriate practices that intentionally promote the active and multimodal nature of young children's learning and language and literacy development in an interdisciplinary context. Consistent with the field, developmentally appropriate practice within edTPA requires that the teacher support the whole child through supportive and challenging active learning experiences that indicate an understanding of the current developmental, cultural, and linguistic strengths and needs of young children. Although the professional organization considers early childhood to be birth to 8 years of age, the Early Childhood edTPA is most appropriate for use in classroom environments with children who are toddlers or older.

Given the importance of language for young children, the Early Childhood edTPA focuses on the candidate's ability to support language and literacy development. Consistent with many early childhood settings, instruction should take place across disciplinary contexts and attend to the interrelated processes of listening, speaking, reading, writing, and visually representing in a learning environment that supports the whole child and provides a healthy, respectful, supportive, and challenging context for learning. Although the full scope of an interdisciplinary and interrelated curriculum may not be feasible in a short learning segment, candidates should construct the learning segment in a comprehensive and integrated way in order to support the whole child and take into account the active, multimodal nature of young children's learning.

Features Unique to edTPA in Early Childhood

The Early Childhood edTPA was intentionally designed and developed to assess candidates' support

of young children's learning. Although state policy may vary with regard to the requirements of teaching placements, including age and grade levels, the Early Childhood edTPA requires the candidate to plan for thoughtful and intentional teaching that promotes the active and multimodal nature of young children's learning. In addition to the subject-specific emphasis, the Early Childhood edTPA has several unique features embedded into the assessment to acknowledge the teaching of young children. Below are a few examples that distinguish Early Childhood edTPA from other edTPA versions.

- Certain terms are used only in the Early Childhood handbook. For example, the term *children* is used in place of *students*; *learning experience* is used in place of *lesson plan*.
- Given the various ways children demonstrate their learning, in Task 3 candidates are required to submit multiple forms of evidence of children's learning to analyze. These sources of evidence should include observation/anecdotal notes, video/audio evidence, pictures, drawings, writing, and so on.
- edTPA assesses academic language and its function in subject matter learning; however, in Early Childhood, the focus is on vocabulary. *Vocabulary* for the purposes of academic language within edTPA is defined as the developmentally appropriate sounds, words, phrases, sentences, and paragraphs that a candidate wants children to use or create to engage in a learning experience.

Each of the differences in the Early Childhood edTPA is intentional and attempts to provide an assessment of authentic teaching practice in the early childhood setting.

edTPA in Early Childhood or in any other content area is not intended to be used by states as the sole measure of candidate effectiveness. edTPA is recommended as part of a multiple-measures system of assessments—so that states ensure that all teachers who enter a classroom are ready to teach on Day One. This approach to recommend candidates for licensure is not only a preparation issue but also an equity and readiness issue.

Benefits of edTPA

State policy makers and teacher preparation programs understand that the future of the public education system resides in its teachers and leaders. All teachers, especially those teaching young children, must understand who they are teaching and the important fact that each child brings unique knowledge and experience into the classroom. edTPA provides an opportunity for candidates to demonstrate their knowledge of their students and their pedagogical approach. Unlike other licensure assessments, edTPA aims to support candidate and program learning, as well as to measure desired outcomes. edTPA provides states and preparation programs with a rich array of resources that support its educative implementation, including handbooks to guide implementation, extensive feedback to candidates and programs, and scoring opportunities for school- and university-based faculty. edTPA complements existing entry-level assessments used by states that focus on basic skills or subject matter knowledge and campus-based evaluations of clinical practice, coursework, grades, and curriculum-embedded assessments of candidate performance. edTPA provides meaningful data to support teacher education programs as they evaluate, reflect on, and continually improve their programs to ensure a rigorous, integrated curriculum centered on student learning.

TEACHER PREPARATION POLICY AND PRACTICE

Teacher education programs use research, theory, and practice to provide individuals with knowledge, skills, and attitudes to educate young children. Early childhood teacher education programs include five components: (1) recruitment and selection, (2) general education, (3) professional foundations, (4) instructional knowledge (Saracho & Spodek, 2003), and (5) field experiences and clinical practice (Saracho, 2013). Most teacher education programs have these components with some variation in their content except for the field experiences and clinical practice. The following sections describe these components.

Recruitment and Selection

The value of early childhood programs depends on the quality and attributes of the teachers. Teacher education programs establish an explicit set of criteria to recruit and select teacher candidates. Their selection process ranges from open admissions to employing a set of standards such as grade point average, standardized test scores,

written profiles, letters of recommendation, and both individual and group interview performance (Casey & Childs, 2007).

The standards-based accountability reforms in early childhood education have generated new challenges for the field (Brown, 2011). The development of accountability requires schools to increase their students' achievement. Therefore, teacher preparation programs need to make critical decisions on their recruitment and selection of teacher candidates to graduate highly effective teachers who can cope with challenging situations and solve problems that go beyond their preparation. The selection and acceptance of teacher candidates suggest that after they have completed the teacher education program they will become highly effective teachers (Clark, 2010).

General Education

General education provides teacher candidates with a unique concept, mode of thinking, structuring of concepts, and preparation. It merges with subjects such as language, social studies, science, communication, social sciences, history, and fine arts. General education helps teacher candidates to develop in the areas of music, art, literature, health, safety, nutrition, physics, biology, mathematics, oral/written communication, technology, and many more. Children's literature is an aspect of literature that is similar to the content areas of art and music. The core of early childhood education depends on the general education disciplines that offer the field's content knowledge. However, this knowledge must be merged and understood to develop a broad perspective in relation to the general conditions of human life (Saracho & Spodek, 2003).

In general education, teacher candidates learn how to help young children explore and interpret their world in a meaningful way, which requires teacher candidates to obtain a broad and liberal education. Lately, technology is considered a discipline in general education. It offers teacher candidates with education and instruction in technology where they learn (a) to use computers in the present digital age and (b) to motivate children to use

computers expressively and in creative ways (Bers & Kazakoff, 2012).

The American Association of Colleges for Teacher Education's (1977) standards for accreditation of teacher education programs recommend that "general education should include the studies most widely generalizable. General studies is taught with emphasis upon generalization rather than academic specialization as a primary objective" (p. 4). Professional accreditation programs of schools, colleges, and departments of education have set up a process to ensure that the teachers are well prepared to become highly qualified teachers (National Council for Accreditation of Teacher Education [NCATE], 2010; now known as the Council for the Accreditation of Educator Preparation [CAEP]).

Professional Foundations

Professional foundations are sources of education such as history, philosophy, sociology, economics, psychology, politics, anthropology, linguistics, and multicultural education. Teacher candidates obtain a broad foundation of knowledge *about* education rather than professional strategies (Peters, 2010). They learn about the history and traditions of early childhood education, principles of child growth and development, learning theory, and various education-related contexts such as cultural, social, and political (Saracho & Spodek, 2003).

Child development is a basic domain in early childhood education. Developmental stages determine young children's approaches to learning and learning processes as well as the selection of developmentally appropriate materials and practices. The National Association for the Education of Young Children (NAEYC) has established developmentally appropriate practices to use as a framework of principles and guidelines for best practice for young children's optimal learning and development (Copple & Bredekamp, 2009).

The federal legislation of the No Child Left Behind Act demanded that early childhood education programs hire "highly qualified teachers." This means that early childhood education teachers learn and understand the range (ages birth to age 8) in young children's development and learning to be

able to offer an effective curriculum and appropriate instruction for them (Copple & Bredekamp, 2009). Professional foundations also provide teacher candidates with knowledge about the children's cultures, languages, and principles that stimulate language and language acquisition. However, general education also provides teacher candidates with this knowledge.

Instructional Knowledge

Instructional knowledge refers to the knowledge that teachers utilize in classroom practice, planning, and evaluation. It provides the teacher candidates with knowledge to select and sequence strategies and methods of instruction in addition to developing educational goals for children. Some teacher education programs integrate aspects of instructional knowledge in different courses, whereas others offer it in separate courses. Instructional knowledge helps teacher candidates learn both knowledge of teaching and knowledge of theories and teaching methods. They learn ways to (a) organize and develop instructional plans, (b) evaluate children and learning, (c) identify individual differences, (d) be culturally sensitive, (e) know the children's cultural background, language, strengths, and needs, (f) use educational resources, and (g) create educational policies and practices (Shulman, 1986). Olivia Saracho (1984) utilizes knowledge of the classroom situation to understand the teachers' professional roles:

- *Curriculum designer* refers to the way teachers develop their curriculum based on theories and practices of early childhood education and the community's interests.
- *Decision maker* refers to the way teachers persistently make decisions about children, materials, activities, and goals.
- *Organizer of instruction* refers to the way teachers utilize educational goals and accessible resources to plan long-range and short-range classroom experiences.
- *Manager of learning* describes how teachers use the learning environment to provide learning experiences based on young children's interests.
- *Diagnostician* refers to the way teachers evaluate the young children's strengths and needs to devise developmentally appropriate and effective learning experiences for them.
- *Counselor/advisor* refers to the way teachers constantly interact with, emotionally support, and provide appropriate assistance to young children.

These roles describe the early childhood teachers' instructional goal and duties. Teacher candidates' effective performance in each role requires them to acquire knowledge, skills, and attitudes to effectively use the principles and practices of early childhood education in the learning process.

Teacher candidates need to know how learning takes place, factors that influence learning, situations for learning, and modifications based on children's needs (e.g., individual needs, interests, attitudes, motivations). In addition, they need to know both curriculum content and instructional strategies that motivate young children to become interested in learning in a variety of educational contexts as well as how to apply developmentally appropriate practices to teach them.

Field Experiences and Clinical Practice

NAEYC (2011) describes field experiences and clinical practice as field observations, field work, practica, student teaching, and other "clinical" practice experiences such as home visiting. A well-planned sequence of these experiences assists teacher candidates to acquire understanding, competence, and dispositions in a specialized area of practice. They also acquire knowledge, skills, and professional approaches that are indispensable in furthering young children's development and learning across the complete developmental period of early childhood from birth to 8 years of age and in different early childhood education settings (e.g., primary grades, child care centers, homes, Head Start).

Field experiences and clinical practice are essential components in the preparation of early childhood education teachers. They integrate collaboration, accountability, and practices related to professional learning. Field experiences provide

teacher candidates with numerous school-based possibilities to observe, assist, tutor, teach, and participate in service learning projects or conduct practical research. Clinical practice includes student teaching and internships that provide teacher candidates with experiences that allow them to totally immerse themselves in the learning community in order to become proficient in their professional roles. Candidate interactions with children's families and communities and their use of technology help them to teach, learn, and perform other professional responsibilities (NCATE, 2008).

Field experiences and clinical practices need to be provided in high-quality settings for teacher candidates to learn and practice. Ideal field placements assist teacher education programs to achieve the goal of preparing well-educated and socialized teachers. Robert V. Bullough Jr. and colleagues (2002) state, "Recognizing the powerful influence school context plays on beginning teacher development, at the same time, effort has been directed toward forging professional development schools: Better schools create better teachers and better teacher education" (p. 68).

Recommendations

Teacher education programs encounter problematic choices in generating curricula, field placements, clinical practices, and assessment methods to prepare teacher candidates to work with children whose ages range from birth to age 8. Too often they disregard preparing teachers to work with children during the critical early years, especially children from birth to 3 years old. Teachers who work in infant/toddler care programs then do not know how to optimally promote learning and development for this age range. When professional preparation focuses only on older children, candidates and novice teachers often attempt to use those curricula and teaching strategies with infants and toddlers and find such applications unsuccessful. Thus, all early childhood education professional preparation programs must include content and pedagogical knowledge as well as field experiences for teaching groups of infants and toddlers.

Early childhood teacher education programs must give attention to teacher quality. Some advocates promote building a support system for teacher quality for both individuals and the entire profession. Suzanne M. Wilson, Jeffrey J. Rozelle, and Jamie M. Mikeska (2011) recommend that to advance toward national standards, teacher candidates need to be provided with learning opportunities that have emerged from thoughtful research focusing on building a system that is rational and influential.

TEACHER ROLES IN INQUIRY

The role of early childhood teachers who are committed to guiding inquiry (their own and that of the children they teach) is informed by their beliefs about young children's competencies, rights, and

passions for learning. Moreover, teacher inquirers are by nature hungry to continually learn new ways to engross children in engaging everyday experiences that embody important questions, ideas, and actions and provoke negotiations toward new meanings. There is no curriculum or single method for teachers to follow. Rather, teacher inquirers embrace a reflexive stance and demonstrate mindful skills characterized by "pedagogical thoughtfulness and tact" that "converts incidence into significance" (van Manen, 1991, p. 187). This entry considers (a) how the image of the child is manifested in teachers' inquiry-oriented practice; (b) how teachers' beliefs, values, and goals influence their decision making during children's moments of inquiry; and (c) how the selection of particular tools, strategies, and approaches characterizes the roles of teachers in early childhood environments where inquiry is encouraged.

Image of the Child

A teacher's image of the child is linked to the decisions she makes when or whether to create the space, time, and opportunity for children's inquiry. For example, teachers who view children as needy and dependent are more likely to view themselves as "the holders of knowledge" who are responsible for giving or transmitting knowledge to children. In these situations, teachers tend to plan and implement activities that are prescribed and closed-ended with little consideration given to children's emerging interests, questions, and ideas. This practice is often developmentally appropriate but implemented *for* the child, not *with* the child. These classrooms tend to look the same year after year with occasional variations in activities and the overall classroom environment. For example, when planning activities for the season of fall, themes of harvest are typical as are animals' preparations for hibernation. Yet, what if children's interests were about how to build and design a bridge over a creek for turtles that live alongside their playground? How would the decisions of a teacher committed to guiding children's inquiry differ from seasonal themes and repetitious activities?

When teachers view children as competent with a large capacity for learning *and* guiding their own learning, the teachers' stance shifts toward nurturers of children's questions and ideas and "bridge builders" between what children know and are coming to know. In these contexts, the curriculum is more fluid, responsive, and relevant, becoming a reflecting pool of particular children's interests, at particular times, in particular places. The Reggio Emilia approach to early education (Edwards, Gandini, & Forman, 1993, 1997) has perhaps influenced and provoked a reconceptualization of early childhood teachers' thinking about our image of the child across the past 25 years, in particular. As Loris Malaguzzi, founder of the approach, noted,

Our image of children no longer considers them as isolated and egocentric, does not only see them as engaged in action with objects, does not emphasize only the cognitive aspects, does not belittle feelings or what is not logical and does not consider with ambiguity the role of the reflective domain. Instead our image of the child is rich in potential, strong, powerful, competent and, most of all, connected to adults and children. (1993, p. 10)

Through embracing an image of the child as strong and competent and a belief that children's voices should be included in pedagogical decision making, a teacher's image of self as inquirer also develops. To engage in inquiry with children, then, means that teachers view themselves as lifelong learners who are poised for new ways of coming to know through coconstructing knowledge with children. Thus, an orientation to teaching *as* inquiry and *for* inquiry emerges and guides curricular and pedagogical decision making, "turning classroom experience into teaching expertise" (Weinbaum et al., 2004, p. 1).

Values, Beliefs, and Goals

Children learn in relation to others through their participation in joint, shared activities mediated by a wide range of tools and language. Teachers who engage in inquiry value the contributions of communities of

learners that resituate the individual within collectives in which teachers are also active participants. Teacher inquirers believe that children deserve opportunities for genuine engrossment in authentic experiences that represent their everyday worlds, their cultures, and their basic identities (Hawkins, 1994). Such rich and relevant experiences are nurtured and propelled by what only others can provide as the "child comes alive for the teacher as well as the teacher for the child" (Hawkins, 1994, p. 60). Thus, through joint inquiry teachers reposition themselves and children away from traditional "power-producing binary divides" toward creating shared space and opportunity for inquiry and reconstructions of self as knower and knowledge (Lenz Taguchi, 2009, p. 161).

In such settings, teachers view children as agentic individuals who have the right to make decisions about their learning lives. Inquiring teachers embrace the role of ensuring that the rights of children to participate in the decisions about what and how they learn and with whom they learn are protected and nurtured. As written in *The Unheard Voice of Children* series, in the publication *A Journey Into the Rights of Children*,

Children have the right to be recognised as subjects of individual, legal, civil, and social rights; as both source and constructors of their own experience, and thus active participants in the organisation of their identities, abilities, and autonomy, through relationships and interaction with their peers, with adults, with ideas, with objects and with the real and imaginary events of intercommunicating worlds. (Castagnetti, Rubizzi, & Vecchi, 1995, pp. 67–68)

An emphasis on active participation with others is central to the development of democratic schooling, originally described by John Dewey (1900), as the ethical imperative of education. This belief is evidenced in the roles of many contemporary teachers who guide young children's inquiry, in whose classrooms the "needed information" and "required discipline" develops (Dewey, 1900, p. 70); "intelligence develops as a result of *reflective, strategic*, real-world problem-solving action and experience" (Benson, Harkavy, & Puckett, 2007, p. 25). Ultimately, the

intent is for knowledge (both content and process) to transcend the intimate and meaningful relationships of teachers and children (Hawkins, 1994, pp. 51–56) and move beyond the borders of early childhood classrooms embodied by children prepared to take charge of their learning as they shape a just and engaged society.

Approaches, Strategies, and Tools

Teacher roles in early childhood inquiry are informed by both pedagogical and principled approaches. Contexts for inquiry are relational, include the active participation of teachers and children, and are focused on a topic of inquiry. David Hawkins (1974) has described this relational triangle as “I, Thou, and It” (1974), a reciprocal, transactional orientation that generates opportunities for teachers and children to engage “in worthy interests and pursuits, . . . through a community of subject-matter and engagement” (p. 52). A critical role of the teacher is to determine which subjects are “worth” investigation and how to pursue relevant endeavors. These decisions are dependent upon careful study, informed by pedagogical documentation and engagement in cycles of inquiry reminiscent of action research cycles.

Pedagogical documentation is the purposeful and systematic generation, organization, and analyses of a wide range of classroom records and artifacts that depict multiple perspectives of children’s and teachers’ activities (Tegano & Moran, 2005). Documentation is generated by teachers through careful observations and artifacts recorded through the use of cultural tools (e.g., audio/video recorders, cameras, maps, and computers) that “freeze-frame” experiences and make visible processes of constructing knowledge for further study. The influence of these representations on the classroom culture is significant. They reveal children’s meaning making; demonstrate a respect for children’s work; validate the competencies of children; and communicate a sociohistorical perspective to parents, teachers, and children of the classroom and school culture.

Documentation is much more than a static record, as it serves as a memory and map of earlier thoughts and actions that inform future learning.

For example, documentation is often used during learning activities as a referent. Children who talk about how to build a bridge for their traveling turtles may also be encouraged to draw their plans or construct a bridge out of blocks while the teacher photographs their steps. Now the drawings, the photographs, and the teacher’s observational notes help her determine how to extend and deepen children’s future building. She may decide to bring the drawings and photographs back to the children to help them reference and recall earlier ideas in order to rerepresent them in increasingly sophisticated ways. As children continue to determine how to build their bridge they generate new documentation through their use of “languages” such as drama, painting, and clay constructions, to name a few. Outside of their classrooms, teachers continue to engage in their own cycles of inquiry or action research cycles characterized by studying documentation, reflecting, planning and projecting new curricula (Mills, 2013). Such action research cycles were first utilized by teachers in the United States in the 1950s inspired by the work of social psychologist Kurt Lewin as a tool for teacher inquiry and informed practice.

Action research is always reflective, often collaborative and discursive, and dependent on classroom data that informs planning and action. Hillevi Lenz Taguchi has described the process of seeking knowledge from the “ongoing material-discursive flow” between social and material entities in learning as “intra-active pedagogy” (Roder, 2011, p. 61). Teachers who strive to understand what steps to take to guide children’s inquiry, therefore, are focused on more than children’s individual and social construction of knowledge but also on how the materials and language intertwine and impact children’s meaning making. Thus, when children are engaged in building a bridge for crossing turtles, the decision on what building materials to give children and the time given for conversation and interaction matters. Materials and classroom artifacts are not neutral and influence the interactions that children have with them and with their peers. Thus, the role of a teacher who guides inquiry is to also focus on these “intra-acts” (Lenz Taguchi, 2009) between the discourse and the materials/artifacts that are embedded

in the performative act of bridge building. Such provision for engagement and representation of the process provides teachers new insights on how to continually reimagine the evolving learning environment that includes diverse “languages of learning” and expressions of thought that reflect children’s developing knowledge, skills, and dispositions (Lather, 1991).

Teachers who draw upon key tenets of the Reggio Emilia approach often refer to the learning environment as “the third teacher” (Edwards et al., 1993, p. 148). One role of a teacher inquirer is to design children’s learning environments to help her teach. Such designs for living and learning (Curtis & Carter, 2003) include situating children in spaces with resources that provide them rich experiences related to their interests, ideas, and questions. Thus, rather than asking children to simply read about whether turtles might use bridges to cross over a creek, an inquiry-oriented teacher would also take children outside to plan and build, revisit and rerepresent those experiences, and return with new theories, questions, and insights.

Such intense and deep study requires a wide range of materials, space, and continuity of experience across time. This kind of setting promotes what John Dewey referred to as an “educative experience” because it leads to “further growth, to further experiencing, to fuller, enriched living” (Cuffaro, 1995, p. 69). Here, his emphasis is focused on the belief that when teachers attend to both the child and the environment, this leads to the creation of new *situations* for learning and studying learning. Much like Hawkins’s “I, Thou, It” and Lenz Taguchi’s “intra-pedagogy,” Dewey’s “situations” include the teacher and child with the material, the artifact, the question, the “It.” Thus, one role of a teacher is to build experiential bridges for children’s inquiry, based on their interests and her growing understandings of their learning processes, illuminated by engagement in cycles of inquiry, pedagogical documentation, and active participation in children’s learning.

A central role of the teacher who guides inquiry is to actively participate alongside children as they learn. Bronwyn Davies (2014) describes what she means by a teacher “being there with children” as

engaging in *emergent listening*. The goal of emergent listening is to participate in children’s inquiry while being receptive to the “not-yet-known” (p. 36). Being there to guide children’s inquiry is “a process of joyful yet unsettling reciprocity that is undeniably temporal and forever incomplete” (Schulte, 2013, p. 4). Thus, teacher inquirers learn to anticipate and tolerate the ambiguity and tension of not knowing where children’s inquiry will lead and depend upon recursive reflective practice of stepping back, reflecting, planning, and acting as they scaffold children’s next steps in knowing.

Scaffolding is a metaphor used to refer to effective ways teachers sensitively guide children’s learning within children’s zone of proximal development (ZPD) (Vygotsky, 1978), or the regions in which a “transfer of ability from the shared environment to the individual occurs” (Berk & Winsler, 1995, p. 24). Scaffolding is often associated with the ZPD, yet was first introduced in 1976 to identify aspects of effective tutoring by David Wood, Jerome S. Bruner, and Gail Ross. Scaffolding refers to the many ways teachers (and peers) support and guide less experienced others’ abilities to reach a level of development that they would not, alone, easily achieve. Scaffolding is a bidirectional, social exchange dependent upon the use of mechanical tools (e.g., objects, maps, drawings, and technology) and language, considered the “quintessential tool of the mind” (Bodrova & Leong, 1996, 2007). Mental tools extend the capacity of children’s minds “to allow them to adapt to their environment, thus having a function similar to that of mechanical tools” (Bodrova & Leong, 1996, p. 17). The role of the teacher is to provide nuanced, informed support to assist a child’s knowledge construction that is just beyond his or her current level of understanding but not so far as to confuse or frustrate the child. This positioning is dependent upon teachers utilizing important components of scaffolding that include joint problem solving, warmth, and responsiveness, keeping children learning within their ZPDs, and promoting self-regulation (Berk & Winsler, 1995, pp. 27–30).

It is also critical for the teacher to know when to intervene (and step back) as children learn new skills and knowledge and work more independently.

Returning to the example of building a bridge for crossing turtles, a small group of children may be unsure how to begin their construction. In this case, a teacher's scaffolding might include a series of posing questions, sharing photographs that show the sequence in their classroom block bridge construction, or providing children pieces of wood, toy turtles, and basins of water in the classroom to encourage experimentation. The materials serve as the "go-between" between previous ways of knowing and the development of new knowledge first generated through shared activity and later internalized. Here, the role of the teacher is to ensure that learning takes place through "a process by which individuals transform their understandings of and responsibilities for activities through their own participation," referred to by Barbara Rogoff (1995) as "participatory appropriation" (p. 150). Thus, it is the ultimate goal of teachers of inquiry to create contexts in which children begin to understand what they know, what they need to know, and how to engage in processes of knowledge construction that move them forward into new contexts of learning.

TEACHER-DIRECTED LEARNING

Teacher-directed learning refers to instruction that is guided by the teacher. The teacher is primarily responsible for creating, planning, and implementing daily lessons and activities for the children to teach specific skills and information. While teacher-directed learning has historically focused mostly on preacademic and academic skills, it can also be used to effectively teach a wide range of skills and concepts including socialization and play.

Philosophy

Teacher-directed learning is based on the philosophy that young children learn more and at a faster rate through planned instruction that is structured and organized with appropriate materials to teach specific content in a clear and systematic way.

Additionally, at young ages, children may not have enough awareness and foundational abilities to independently seek knowledge and thus require guidance from a teacher to learn new skills and concepts. Furthermore, some skills and concepts would be difficult to learn through discovery. Finally, formal instruction led by teachers can prepare young children for later school experiences.

Theory

With a base in behavioral theory, teacher-directed learning emerged from the concept that if teachers act in certain ways, students will respond in certain ways. Teachers conduct learning activities and provide appropriate feedback and consequences for children's responses. Building on that view with a cognitive perspective, teachers not only conduct activities but provide specific opportunities for learning and then help individual children interpret information gained from the experience. Finally, with social learning theory as a guide, teachers also become responsible for developing a community of learners as children are provided with opportunities to interact with others in the environment.

History

Traditionally, teacher-directed learning translated into the teacher giving a lecture while the role of the student is to passively listen to the information being presented. In the early 1900s, with the emergence of the constructivist perspective, child-initiated learning emerged as an alternate and opposing teaching practice, especially for young children. In early childhood education, teacher-directed learning has been linked with achievement of preacademic and academic skills while child-initiated learning has been associated with learning through play. Recently, with a focus on accountability in education (e.g., No Child Left Behind Act), there has been a shift back to teacher-directed learning to better ensure that children meet early learning curriculum standards. While many embrace the teacher-directed versus child-initiated dichotomy of learning and debate the merits of each practice, current best practice calls for a

combination of approaches where both teacher-directed learning and child-initiated learning can occur in early childhood. Indeed, developmentally appropriate practice can be used to guide the balance of the two types of learning in early childhood classrooms to meet the educational needs of young children.

Key Components

Teacher-directed learning includes several key components. These components are as follows:

The Teacher Is the Leader in the Classroom. While the “teacher” generally refers to the lead or primary teacher in the class, when interacting with the child, the teacher can also be an assistant teacher, other professional staff, or any other adult (e.g., parent, volunteer) that has been given information about the child’s or children’s educational plan.

The Teacher Establishes and Enforces Rules in the Classroom. Typically, in early childhood classrooms that utilize teacher-directed learning, the classroom environment is generally more organized, structured, and quiet than those that primarily use child-initiated learning. The teacher usually employs behavioral management techniques to support positive behaviors in the classroom. For instance, the teacher may set up classroom rules and have children practice following those rules. For older children, an effective strategy is for the early childhood teacher to create the class rules with the children by soliciting input about appropriate classroom behavior. The teacher then provides appropriate consequences for the behaviors observed. These consequences can include reinforcement such as praise, stickers, or other rewards for positive behaviors. When possible, consequences should be natural and tied to the behavior. For example, if a child independently says “please” when requesting a toy, efforts should be made to give that toy to the child. If a child refuses to clean up toys, the child is not allowed to participate in the next activity.

The Teacher Determines the Learning Objectives. While the learning objectives in an early childhood

classroom should be aligned with state and school standards and influenced by family priorities as well as child interests, strengths, concerns, and current skill levels, the teacher ultimately decides the curriculum for each lesson every day. There may be learning objectives for the entire class of children, and there may also be individual learning objectives for each child. Regardless, learning objectives are clearly stated in lesson plans and are changed in a systematic way dependent on children’s response to the learning activity. Learning objectives can cover preacademic and academic skills such as shapes, counting, and letter recognition. However, in early childhood, they should also address other developmental domains such as communication (e.g., speaking, understanding instructions), social (e.g., turn taking, following directions, playing), motor (e.g., drawing, ball throwing), and self-help/adaptive skills (e.g., handwashing, coughing in elbow).

The Teacher Structures Learning Tasks and Establishes the Time and Method for Task Completion. After the learning objectives have been defined, the teacher selects learning activities for the children in the classroom. Instruction can be delivered by the teacher in a large group (e.g., circle time with the whole class), in small groups (e.g., centers), or individually in a one-on-one format. Different activities take place throughout the day according to a schedule. Materials for learning activities can include the use of flashcards, worksheets, and file-folder activities as well as books, manipulatives, music, art supplies, games, and toys. The teacher specifically plans how children should interact with the materials and helps facilitate those interactions in order to meet the learning objectives.

The Teacher Actively Maintains Student On-Task Involvement. For the teacher to effectively teach a child, the teacher must explain or demonstrate the target skill or concept explicitly to the child. Furthermore, the teacher should provide multiple examples so that children can learn and generalize the skill or concept. With teacher-directed learning, children are also given a chance to practice or demonstrate their understanding with guidance from the teacher before practicing independently.

The Teacher Presents Clear Expectations for the Child. In each learning activity, instructions are clearly stated so that there is no ambiguity. Larger tasks are broken down into smaller steps for the child to follow. If the teacher is asking questions, the questions are specific, such as “Which one do you want?” “What color is this?” and “Whose turn is it?” Therefore, for each activity, a specific range of appropriate responses is expected.

The Teacher Responds to Students With Feedback. Through clear and direct feedback, teachers guide children to learn new skills and concepts. Teachers provide immediate reinforcement (e.g., praise, rewards) for appropriate responses to learning activities. For incorrect responses, teachers use prompts and cues to help guide children to correct responses. The level of prompting given is determined by the child’s response. If the child is only slightly struggling, the teacher may just give the child a little hint. If the child is having a great deal of difficulty, the teacher may model or physically help the child demonstrate the correct response.

Balancing With Child-Initiated Learning

A teacher-directed learning program can also incorporate components of child-initiated learning in the early childhood classroom. Early childhood educators can use developmentally appropriate practices to determine how to balance and use both teacher-directed and child-initiated learning in the classroom.

To integrate and embed features of teacher-directed learning into child-initiated activities, teachers can set up the environment, use incidental teaching, follow a system of least-to-most hierarchy of prompts, and deliver natural consequences. First, teachers can set up the environment by providing materials related to the learning objective. Second, with incidental teaching, teachers can take advantage of naturally occurring opportunities to practice the target skills or concept. Third, with a least-to-most system of prompting, teachers first allow the child to independently demonstrate a

skill. If the child is having difficulty, the teacher gives a nonintrusive hint before directly helping the child achieve the task. Finally, consequences should be natural in that they should be directly related to the task. For example, if the child asks appropriately for a turn with the toy car, the child should be rewarded by getting a turn to play with the toy car rather than receive a sticker.

Best Uses of Teacher-Directed Learning

The use of teacher-directed learning may be more effective with some individuals than others. Children who may benefit most from teacher-directed learning are those children that do well with structure and organized environments. For young children who are easily overwhelmed and have difficulty exploring and interacting with materials in the classroom, the clear expectations and specific tasks may provide comfort to the child that would then facilitate the child’s learning. Teacher-directed learning is also beneficial when the learning objectives are mostly skill based.

For teachers, being systematic and able to organize and structure learning tasks is a prerequisite for teacher-directed learning. The teacher should be able to plan detailed lessons and provide appropriate feedback to children’s responses. For teachers who may be uncomfortable following children’s lead and quickly turning children’s actions into learning activities, teacher-directed learning may allow the teacher to feel confident in the classroom. Specifically, novice teachers may be more effective in using teacher-directed learning than child-initiated learning when given a prescribed curriculum and learning tasks to implement in the classroom.

Research

Research has shown that early childhood programs with more teacher-directed learning can result in larger cognitive gains early on as well as higher achievement of new skills and concepts. Teacher-directed learning has also been associated with later success in school. There is a lack of

research regarding children's social-emotional outcomes with teacher-directed learning. However, research does indicate that teacher-directed learning can be particularly effective in teaching young children with special needs, including young children living in poverty.

TEACHING TEAMS

Staffing with teaching teams in center-based early childhood classrooms and large family child care programs reflects the pedagogical challenges of providing developmentally appropriate and individually responsive programming for diverse groups of children and families as well as compliance with licensing regulations for teacher-child ratios. Not all collections of adults working together, however, constitute a teaching team. A teaching team is a stable group of adults who share goals and responsibilities for the children and families they serve.

Composition of Teaching Teams

Membership of a teaching team is typically determined by an administrator based on qualifications and availability of individuals, or teaching teams may be more purposefully constructed. In the latter case, teaching teams may include members whose personal or specialized educational backgrounds complement those of others on the team to increase the collective competence of the team. For example, in a bilingual, immersion, or two-way bilingual classroom, one team member may be a native speaker of English and the other a native speaker of another language; or in an inclusive classroom, one may be a general educator and the other a special educator; or a team member with close ties in the community may be teamed with one from outside the community who brings other strengths. In some cases, staff members may request to work together in a teaching team because of individual affinities.

Although most often the term *teaching team* is applied to groups of adults who serve the same group of children for most or all of a day, external providers of special services such as speech therapy, occupational therapy (OT), and physical therapy (PT) in inclusive classrooms who enjoy stable relationships with the classroom staff over time and where communication with the staff is substantial may be considered members of a teaching team as well. The term *teaching team* may also be applied

to cross-classroom teaching teams who serve children of the same or similar ages. In such teaching teams, responsibilities for curriculum planning may be distributed, joint learning experiences planned, and use of shared materials and spaces negotiated.

Composition and Structure of Teaching Teams

Teaching teams may be composed of lead or head teachers, coteachers, teaching assistants, assistant teachers, or aides. Each of these roles differs in terms of status, power, and responsibility within the team. These distinctions may be based on educational qualifications, specialty areas, years of teaching experience, and years of service in a particular site. The clarity and stability of the roles and responsibilities of each member of a teaching team will vary across early childhood education settings and across individual teaching teams within a setting.

The structure of a teaching team may be either explicitly or implicitly hierarchical or intentionally democratic and collaborative. In hierarchical structures, lead or head teachers may take primary responsibility for curriculum planning, child assessment, family contact, and administrative tasks. Assistants and aides may participate, to varying degrees, in these responsibilities. However, most often, they provide support in the form of facilitating learning activities planned by the teacher, assisting in the preparation and care of materials and the classroom space, record keeping, and providing coverage during break times.

In teaching teams structured as collaborative partnerships, power and responsibility are explicitly shared. Members of coteaching teams work collaboratively in planning and implementing curriculum, child assessment, and family partnerships within their classroom. Marilyn Friend and Lynne Cook describe six ways in which two-person coteaching teams may share responsibility for instruction:

1. *One teach, one observe* and gather observation data
2. *One teach, one assist* by providing unobtrusive assistance
3. *Parallel teaching* in which the group is divided and both lead the same learning activity
4. *Station teaching* where one is responsible for a learning experience with one group of children and the other provides a different learning experience for another group of children
5. *Alternative teaching* where an alternative learning opportunity is provided for a small group of children while the other teacher is responsible for the majority of the group
6. *Team teaching*, the most sophisticated teaching team structure, in which both lead learning experiences together is a style often referred to as “one mind, two bodies”

Successful teaching teams establish and maintain clear and honest communication and develop relationships based on mutual trust and respect. Sufficient time for fulfilling shared responsibilities is required, as are regular times for unhurried discussions of goals, strategies, and outcomes of their work together.

Impact of Teaching Teams

Structuring staff in teaching teams has the potential to positively impact children, program quality, and in-service and preservice educators. Although the potential for impacting children is widely acknowledged, the great diversity in definition, composition, structures, and daily practices of teaching teams has made empirical study difficult. Of the studies that have been conducted, many have focused on coteaching in bilingual and special education programs with uneven findings.

Teaching teams are also considered potentially productive sites for professional development and program improvement. When teaching team members attend professional development experiences together, new knowledge and skills are more likely to be applied in their classrooms. Regular focused reflective conversations within teaching teams about their children, curriculum, teaching strategies, or engagement in formal inquiry about their practice can yield ongoing

and contextually relevant professional development and program improvement.

Teaching teams are also considered fertile ground for preservice professional development. When preservice early childhood teachers are included as members of a teaching team, they take on roles that evolve over time to include greater responsibility. Recent work on structuring capstone clinical placements as coteaching teams shows particular promise. Including preservice teachers in teaching teams both supports learning to teach and prepares them to participate as future members of teaching teams.

TECHNOLOGY AND PLAY

Children need to engage their imaginations to construct or create through play. But meaningful play is not possible without adult guidance and carefully chosen materials, objects, or props. Adult involvement should be much more than playing with and observing children. Teacher and parent roles should provide real-world experiences to set up the motivation, scaffold the play with objects or new ideas, and carefully selected play props that will support meaningful and mature play (Johnson, Sevimli-Celik, & Al-Mansour, 2013).

Children may play with only their imaginations or may extend their imaginations through the uses of natural, found objects such as sticks or human-made objects such as toys, balls, cards, board

games, and increasingly in recent years, interactive media devices, such as cell phones and tablet computers. The concept of “toys” has changed over time as contemporary technologies become available to enhance play opportunities, but Seymour Papert (1996), an early innovator and supporter of home and school technology, has said that “our concern must be to ensure that what is good about play is at least preserved (and hopefully enhanced) as the concept of ‘toy’ inevitably changes” (p. 188).

Challenges of Play With Technologies

The research on the importance of mature play with nontechnology objects is widely accepted to enhance children’s learning and development of self-regulation (control over actions, emotions), social competence with peers and adults, physical fitness, and other cognitive abilities such as problem-solving and creativity (Johnson et al., 2013). In contrast, there are fewer consensuses about the research on play with media, yet the numbers of young children with access to technologies is rapidly increasing. *Zero to Eight: Children’s Media Use in America*, a nationwide survey of parents by Common Sense Media (2013), reported that 38% of children under age 2 have used a mobile device for media (compared with 10% in 2011). Seventy-two percent of children age 8 and under have used a mobile device for some type of media activity such as playing games, watching videos, or using apps, up from 38% in 2011. The Cooney Center’s report found that 67% of 8-year-old children in their study use the Internet on a daily basis (Gutnick, Robb, Takeuchi, & Kotler, 2011).

Some experts, teachers, parents, and families challenge the uses of technologies for infants, toddlers, and preschool children. They point to the possible harmful effects of excessive uses of electronic media on young children’s development, that is, lack of impulse control, obesity due to inactivity, and attention-deficit/hyperactivity disorder. Some play advocates, parents, researchers, and teachers view society as a “media saturated, fast paced world” and support efforts to “take back” childhood so they can engage in good old-fashioned make-believe playtime during critical periods of

language, social skills, and self-regulation development (Singer, Golinkoff, & Hirsh-Pasek, 2006). Without proper adult guidance on types and amount of use, there is evidence that the use of computers, mobile devices, and TV can replace young children's authentic play with objects, interacting other children, and time outdoors in active play (Levin, 2013).

Benefits of Play With Technologies

All "screen time" does not have the same impact on play; computer use and TV viewing do not impact learning in the same ways. Mitchell Resnick (2006) suggests that computers and their uses should be considered more like paint brushes to create, imagine, and play than like TVs for passive viewing. Multiple research studies do report the benefits of carefully selected developmentally appropriate and interactive technology tools and materials to enhance children's learning and development in language skills, enhanced dramatic play, understanding of spatial perception, peer interactions, and collaboration—those same qualities as playing with nontechnology toys (Hartle & Berson, 2012; Yelland, Hill, & Mulhearn, 2004).

The potential of technologies to support play requires making informed decisions about appropriate scaffolding with all high- and low-technology tools. Lack of preparation by parents and teachers of young children on strategies to effectively and appropriately use technologies to support play and learning is a challenge (Barron et al., 2011), but guidelines, online references, and professional development are available.

NAEYC and the Fred Rogers Center for Early Learning and Children's Media at Saint Vincent College (2012) completed a revised position paper on technology for young children: *Technology and Interactive Media as Tools in Early Childhood Programs Serving Children From Birth Through Age 8*. The key messages in this position statement support the research that when used intentionally and appropriately with limitations to time spent and when carefully chosen related to the child's development, technology and interactive media are effective tools to support learning and development.

Other resources provide clarifications regarding ages when children are most vulnerable and what families can do to play a more active part in children's uses and time balanced with active play and effective technology uses (Fred Rogers Center for Early Learning and Children's Media at Saint Vincent College, 2012; Guernsey, 2012; Simon & Nemeth, 2012).

Technology and Digital Media in the Early Years: Tools for Teaching and Learning (Donahue, 2014) presents distinctions about specific uses of technologies and explains how children can use media and hands-on materials to do what they do best—explore and discover through play, such as by engaging in virtual field trips, which enrich children's experiential base; and playing open-ended video games, which enrich vocabulary and mathematical problem-solving skills. Teachers and parents can further educate themselves by using the *Checklist for Identifying Exemplary Uses of Technology and Interactive Media for Early Learning: The Pennsylvania Digital Media Literacy Project* to evaluate technology choices that will enhance play (Robb et al., 2014).

Even the youngest children are engaged in the contemporary "participatory" culture through technologies uses and the Internet (Jenkins, 2006). Young children are capable of researching information on the Internet using multiple texts, both virtual and concrete types of play objects, and then repurposing or representing or sharing their creative ideas in "one hundred languages" (Edwards, Gandini, & Forman, 1998), or modes of expression. In the rapidly changing digital world, children in contemporary classrooms and homes engage in transmedia play experiences (Herr-Stephenson, Alper, & Reilly, 2013). Children explore across mediums and remix settings, plot elements, and characters from videos, toys, and online games using any combination of digital, verbal, musical, written, drawn, or painted texts. Examples include taking and using digital photos to research a topic to make props for their play, using software to create books, or making movies of their play so they can revisit and reflect upon the scenes and hence broaden their language and knowledge base to share new stories (Hartle & Jaruszewicz, 2009). High-quality practices do not supplant but

rather supplement and enhance play and learning. One early learning and development center director who follows these best practices reports that children in his center are engaged with all mediums in their play; the technology is there and available, but the technology is an invisible, seamless support to authentic play and learning (Jackson, 2011), which is as it should be.

Conclusion

Since technologies are a central part of society and may be even more so in the future, researchers, teachers, and families will need to continually scrutinize relevant research on how well, when, where, and why to use technology with young children (pros and cons). To support child learning and development through play, careful consideration should be given to the selection of emerging digital literacies considering the child's development level and interest, the content of the digital media, and the context of the play.

TECHNOLOGY IN EARLY CHILDHOOD EDUCATION

In 2012, the National Association for the Education of Young Children (NAEYC) and the Fred Rogers Center for Early Learning and Children's Media at Saint Vincent College issued a

joint position statement titled *Technology and Interactive Media as Tools in Early Childhood Programs Serving Children From Birth Through Age 8*. The statement is grounded in the developmentally appropriate practice framework (Copple & Bredekamp, 2009) and defines effective, appropriate, and intentional use of technology and media with young children. The principles and guidelines provide guidance to the field and for early childhood educators and caregivers on the selection, use, integration, and evaluation of technology tools for learning in early childhood settings.

Key principles include the following:

- When used intentionally and appropriately, technology and interactive media are effective tools to support learning and development.
- Intentional use requires early childhood teachers and administrators to have information and resources regarding the nature of these tools and the implications of their use with children.
- Limitations on the use of technology and media are important.
- Special considerations must be given to the use of technology with infants and toddlers.
- Attention to digital citizenship and equitable access is essential. (NAEYC & Fred Rogers Center, 2012)

Since early 2012, when the position statement was published, a number of leading early childhood organizations released their own reports, policy briefs, recommendations, and guidelines for best practice. In 2014, the RAND Corporation published the report *Using Early Childhood Education to Bridge the Digital Divide*, as well as a series of follow-up reports that explored ways for early childhood education and educators to bridge the digital divide, redefine developmentally appropriate use, identify goals for technology use, describe an adequate technology infrastructure, provide training and professional development, and improve family engagement.

Also in 2014, ZERO TO THREE issued a report, *Screen Sense: Setting the Record Straight*. The report provides an evidence-based review of what we know about the effect of screen media on

young children's development and learning and research-based guidelines for screen use for children under 3 years old. The report and accompanying materials help educators and caregivers make informed choices about the appropriate use of technology and digital media in the early years, by addressing the often-conflicting advice about screen use by children birth to 3.

Early in 2015, the HighScope Educational Research Foundation released a position statement on young children and technology, *Using Technology Appropriately in the Preschool Classroom*, based on the principles and practices of the HighScope curriculum and grounded in a review of the research on children's use of technology. The statement provides guidance for early childhood educators as they make programmatic decisions and identifies guidelines for evaluating the use of technology by taking into account what we know from the current research.

Taken together, these diverse perspectives from leading early childhood organizations provide a strong foundation for early childhood educators interested in integrating technology in the classroom. They begin to identify and describe what we know from research on children's media and early learning and help situate the conversation about technology use with young children in the broader context of new and emerging early childhood practices with technology and digital media.

Technology in Early Childhood Education: What Matters

A synthesis of the position statements, reports, research reviews, and recommendations from NAEYC, the Fred Rogers Center, RAND Corporation, ZERO TO THREE, and HighScope identifies a set of foundational elements necessary for successful technology integration with young children. For early childhood educators and the field, the takeaways about what "matters most" include the following.

Addressing Concerns Matters

The concerns that have been raised by parents and educators about technology use and young

children need to be acknowledged and thoughtfully addressed to reduce the potential for negative impacts on healthy growth, development, and learning. Common concerns about young children and technology include the amount and kinds of screen time; the amount of passive media use; exposure to inappropriate content; commercial messages that target children; the displacement or replacement of developmentally essential materials, activities, and experiences; a decrease of imaginative and open-ended play, active learning, hands-on learning, and creativity; social isolation and a negative impact on social and emotional development; increased digital distractions leading to interrupted adult-child relationships; less outdoor time; decreased physical activity and increased childhood obesity; sleep disruptions; the impact of "always on" technology and background TV; and other health concerns. The field has also acknowledged the need to address access and equity issues so that new digital devices become tools for all children and families that can help close the achievement gap and narrow the digital divide.

Early childhood educators need to be mindful of these concerns and the potential for negative impacts even as they promote positive experiences with technology and media through the appropriate and intentional selection, use, integration, and evaluation of technology tools for learning in the classroom.

Early Childhood Education "Essentials" Matter

Educators need to be sure that technology and media do not displace or replace active playtime outdoors; hands-on activities with real materials and loose parts; authentic and deep engagement; and creative expression through art, music, and movement. During the early childhood years, young children need interactions and relationships with caring adults and other children. They need a balance of solitary and shared experiences. Early childhood should be a time of creativity, curiosity, inquiry, and wonder. Open-ended exploration; unstructured, active, imaginative play; and time outdoors and in nature are essential. Appropriate and intentional selection and use of technology

should enhance and extend essential classroom materials and experiences, offer another tool for learning, and empower young children as learners.

Families Matter

Early childhood educators have long understood how much families matter to the healthy growth, development, and learning of young children. In the digital age, how families access and use media in the home also matters. How children use media at home reflects their interests and needs and is strongly influenced by family needs, backgrounds, languages, cultures, communities, attitudes toward technology, access to technology and a broadband connection, and the media habits of the adults in the home. Digital age educators have an opportunity to help families develop healthy media habits and strive for positive family media ecology in the home. Educators can also use technology tools to improve communications, strengthen home-school connections, and enhance family engagement.

Relationships Matter

In early childhood, the interactions with others that lead to relationships with peers and caring adults are central to healthy development and learning. Educators understand that young children learn best in the context of interactions and relationships with tuned-in, responsive, and caring adults. Technology tools should strengthen a child's relationships with caring adults and peers, not disrupt or interrupt them. Appropriate and intentional use of technology tools should support children's development and learning, strengthen relationships, encourage prosocial behaviors, and promote social and emotional development.

Social and Emotional Development Matter

A whole-child approach to early childhood education emphasizes social and emotional development along with the domains of cognitive, language, and physical development. Classroom use of technology often focuses on curriculum areas such as early literacy, science, and math, but social and emotional skills such as persistence, self-control,

curiosity, grit, and self-confidence are also related to academic and personal success. Educators who consider the whole child can be mindful and intentional about how technology tools support all developmental domains and can look for technology tools and content that help build executive function skills and develop the social and emotional skills children will need for living and learning in the 21st century.

Joint Engagement With Media Matters

Adult-child interactions are key to language learning and learning with media. When adults and children share an experience with a book or with media, the learning opportunities are enhanced. Joint engagement also refers to opportunities for peer-to-peer learning when more than one child uses a computer or tablet. Educators should look for technology tools and content that invites and encourages joint engagement.

The Individual Child Matters

Educators need to choose the right technology tools, content, and experiences for each child's needs, abilities, interests, and developmental stage. These are decisions educators know how to make and are already making many times a day in their classrooms with regard to traditional materials such as blocks, small manipulatives, and books. Selecting and using technology tools is no different. Educators who can connect their understanding of child development theory and the principles of developmentally appropriate practice with knowledge of the individual child can match the right technology tool and content to the child to achieve goals for learning and development.

Content Matters

The quality of content on the screen also matters in early childhood settings. Quality digital content actively engages and empowers young children; combines child control with guided exploration; encourages interactions and offers opportunities for joint engagement; extends and enhances essential experiences and learning opportunities; connects

on-screen and off-screen experiences with real materials in the classroom; and allows the child to save, revisit, revise, print, and share his or her work. As with other appropriate materials offered to children, digital content and screen experiences should be meaningful, hands on, culturally appropriate, and inclusive; should include appropriate images and language; and should accommodate children of different abilities and needs. With quality content, “what children watch and do” on screens is more important than “how much” or “how long” they watch.

Context Matters

An established principle of early childhood education is that children learn best in active environments when they are engaged in meaningful, interactive, and social contexts, and the same considerations need to inform instructional practices and technology use. Educators need to be aware of, and intentional about, the context—who, what, when, where, how, and why—of technology use in the classroom to be sure it complements and builds on children’s natural play patterns and interactions.

Creating Media Matters

In the 21st century, it will not be enough to know how to use technology to consume media. Young children are capable of creating their own messages and expressing themselves through media when they have control and the opportunity to progress from consuming media to meaning making with media to creating media. Early childhood educators who gain digital media literacy and fluency can progress from media consumers to creators who are better able to guide young children along this continuum toward media creation.

Technology Integration Matters

The goal of technology integration in classrooms and early childhood settings is not to displace or replace essential activities and experiences offered within a whole-child approach. When technology is integrated appropriately and intentionally, the goal is to enhance and expand essential activities and

experiences and to provide universal access to powerful tools for learning in new ways and for all children.

Applying Guidance on Technology in Early Childhood Education

Understand What We Already Know

The field of early childhood education already has a solid foundation upon which to base decisions about and use of technology and digital media in the education of young children. The first step toward appropriate and intentional practice begins by applying what we know about child development, early learning, developmentally appropriate practices, cultural and linguistic diversity, and the influence of family and community. With this foundational knowledge educators are equipped to make mindful choices about technology use and integration in the classroom.

Learn About the Guidelines, Recommendations, and Best Practices

Valuable guidance is available to the field. The joint position statement from NAEYC and Fred Rogers Center, reports on policy from the RAND Corporation, recommendations from leading early childhood organizations such as ZERO TO THREE and HighScope, and more than 40 years of children’s media research provide principles and guidelines to help educators select, use, integrate, and evaluate technology effectively, appropriately, and intentionally. Connected educators also know how to communicate and collaborate with other educators in online communities and on social media to share stories, exchange resources, and identify best practices.

Know What Matters

What we know matters most for healthy growth, development, and learning in the early years informs what matters most when integrating technology. For young children and technology, that includes acknowledging concerns about the effects of technology and understanding the

importance of essential early childhood experiences, families, relationships, joint engagement with media, the whole child, and the individual child. The quality of the content, the context for media use, the opportunity for young children to create media, not just consume it, technology integration, and digital media literacy are also at the heart of intentional and appropriate use of technology with young children.

Strive for Digital Media Literacy and Fluency

In the 21st century, young children need early childhood educators who have the confidence and commitment to improve their own skills and become digitally literate and fluent. These digital age educators know how to intentionally and appropriately select, use, integrate, and evaluate technology for the classroom and for individual children. This means having a positive disposition toward technology tools for learning and gaining sufficient knowledge, experiences, and competencies with technology tools and media to support and guide 21st-century learners and their families.

Become Media Mentors

Young children and their families need information, resources, support, and encouragement from enthusiastic digital tour guides, effective role models, and media mentors. Early childhood educators in formal and informal settings have the opportunity to model appropriate and healthy use of technology and digital media to the young children who watch how, when, and why the important adults in their lives use technology and media. Educators can become media mentors who support families by becoming trusted sources for resources and recommendations on technology and interactive media, advocating for a healthy media diet at home, and helping families become media mentors to their own children at home.

Use Technology as a Tool

Early childhood educators can turn the principles from the NAEYC and Fred Rogers Center position statement into action steps, such as

- using technology and digital media intentionally and appropriately as tools to support learning and development of all children and as tools to enhance family engagement;
- learning more about the nature of technology and digital media tools to understand the implications of their use with children;
- placing limitations on the use of technology and media in the classroom by applying the same criteria used for the reading area, block corner, or dramatic play area;
- giving careful consideration to the use of technology with infants and toddlers; and
- paying careful attention to digital citizenship and equitable access for all young children and families.

To realize the potential of technology and digital media as tools for learning, early childhood educators need to take individual and collective steps toward digital media literacy. This is not a solitary journey. The pathways toward digital media literacy, appropriate and intentional practice, and effective technology integration are shared with all the other early childhood educators, teacher educators, professional development providers and trainers, administrators, curriculum coordinators, families, caregivers, and media developers who are also scrambling to catch up and keep up in the 21st century. Many of the adults who work with and on behalf of young children today were not born into the digital age, but all of the children in early childhood programs are growing up in a digital world with new tools that create new opportunities for learning if they have mindful media mentors to guide the way.

Control and Prevention (CDC). In addition, the CDC reported that 305,388 babies were born to teenagers in 2012. This equates to a live birth rate of 29.4 per 1,000 women in this age group, representing a record low for U.S. teens, and a drop of 6% from 2011. Issues related to teen pregnancy usually fall into five categories: (1) emotional, (2) social, (3) educational, (4) financial, and (5) health related.

Emotional Issues

Since many teenage pregnancies are unplanned, the first challenge faced by teen parents involves the decision about how to deal with the pregnancy. Most schools offer resources to help teenage parents make informed choices about how they will address this issue. Depression, frustration, fear, and anxiety are some of the emotions that males and females experience when facing an unplanned pregnancy. According to a research article published in the *Journal of Pediatric and Adolescent Gynecology* in 2010, over 25% of pregnant teens will experience some type of depression. Depression is impacted by a number of factors, including whether the teen mom is still involved with the child's father, and whether her or her partner's families are supportive with whatever decisions are made concerning the pregnancy.

Social Issues

Teenage pregnancy creates social issues as well. Teens that are pregnant have fewer opportunities to date, participate in school activities, and just hang out with friends. This becomes an even bigger concern once the child is born because now the teen parents have to consider the financial and emotional needs of their child. In addition, the stress of having an unplanned pregnancy can be challenging to any relationship, and therefore, some teenage mothers feel alone and isolated from their friends. Opportunities for social activities are also limited as new parents face challenges supporting the child and finding appropriate child care while they are working or going to school.

TEEN PREGNANCY AND PARENTING

Teen pregnancy rates in the United States have fallen in recent years, but the country still has a higher rate than any other developed country, according to data by the Centers for Disease

Educational Issues

Statistics from the National Campaign to Prevent Teen and Unplanned Pregnancy show that 40% of young women who have babies before they are age 18 ultimately drop out of high school. This results in a mother having less education and a lower paying job, and it diminishes the prospects for future earnings. While schools no longer require girls to drop out when they become pregnant, it still creates a burden on teen moms who try to remain in school, since they have the added responsibility of taking care of a child. Fortunately, many schools now have programs that support teenage parents, such as in-school child care, parenting classes, and counseling to help teenage parents cope with their new responsibilities. In addition, there are programs such as YouthBuild that are designed to help students who drop out of school. YouthBuild is a national organization designed for low-income students ages 16 to 24, which simultaneously addresses core issues facing low-income communities: housing, education, employment, crime prevention, and leadership development. In YouthBuild programs, low-income young people work toward passing a high school equivalency exam, learn job skills, and serve their communities by building affordable housing.

Financial Issues

According to the March of Dimes, over 50% of children born to teenage mothers live in poverty, and 75% of unmarried mothers will access welfare/public assistance by the time their child is age 5. Because they lack the education or experience to get a job that will support them, teen parents often struggle financially. They may depend on family members or government programs to help support their child financially. Any expendable income a teen parent may have had in the past will likely go toward caring for her child as opposed to entertainment, fun, or buying new clothes. Additional financial concerns include paying for the delivery of the child, finding affordable housing, and paying for necessities such as diapers, food, and medication. There are a few government programs available to help with these issues but most do not cover all the costs.

Health Issues

Teenagers are at risk for complications during pregnancy such as premature birth, low birth weight, and sudden infant death syndrome (SIDS). Babies born early or small are also at risk for continuing health problems after birth, causing additional stress. There are additional life choices that can adversely impact a teenage mother, such as the use of alcohol or drugs and lack of prenatal care. Any one of these factors can result in premature birth, low birth weight, or even a more serious complication such as fetal alcohol syndrome (FAS), a condition in which a child is born addicted to alcohol. Babies with FAS are born with physical and mental defects that develop in the fetus as a result of mothers' high levels of alcohol consumption during pregnancy.

Strategies

First of all, it is very important that a teenage mother access health care as soon as possible. Laws are now in effect in some states protecting underage mothers from having to inform immediate family members about their condition. However, often a teenage parent's family can be a strong support system. State, county, and local departments of public health offer free services, which include pregnancy tests, prenatal consultations, and informational booklets about teen parenting. Other helpful resources include the following:

- Organizations designed to support teen parents. For example, Planned Parenthood is a national organization with many resources for pregnant teenagers. In addition, this organization offers counseling services for pregnant teens, providing advice on pregnancy termination, adoption, and parenting. Planned Parenthood operates more than 800 health care centers across the United States, making it the nation's number one sexual and reproductive health care provider. Research indicates that 23%, almost one-fourth, of Planned Parenthood clients in the United States are under age 20.
- Many schools have special programs for teen parents that include face-to-face support groups

as well as an in-school child care facility. If the local school does not have such a program, there are often options to transfer to one that does.

- The Generations Program gives teenage parents and their children access to health care. It serves parents 18 and younger, or 19 and younger with special needs children. This program is designed to partner with community-based services for teenage parents and provides services such as immunizations, parenting education, and physical checkups for parents and their children.

- The Internet also provides options for teenage parents. There are many websites, forums, and online communities that are devoted to the issue of teen pregnancy. These sites are places where pregnant teens can go to learn more about their condition and to interact with others in a similar situation. YoungMommies.com is one such site, designed to offer support and to provide information to pregnant teens.

- There are government programs designed for low-income mothers as well, such as the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), a nutrition program for low-income families. Although federal grants fund WIC, state and local agencies administer the program at the local level. WIC funds provide assistance for buying nutritious foods, educational resources, counseling, and referrals to other social service agencies designed for low-income families.

- For financial assistance, Temporary Assistance for Needy Families (TANF) is a federally funded financial assistance program for low-income families with dependent children and for pregnant women in their last 3 months of pregnancy. This program, which is administered by states, provides temporary financial assistance while also helping recipients find jobs that will allow them to support themselves.

TEMPERAMENT

The idea of temperament resonates with parents of infants and very young children who observe how their children respond to new encounters in

their world. Defined as an individual behavior style that is both biologically and environmentally determined, *temperament* is most often understood through the three types first identified in the research of Alexander Thomas, Stella Chess, and Herbert Birch in 1970 and maintained throughout their research into the 1990s:

- *Easy* children are positive in mood, adaptable, and moderate in their reactions, enjoy regularity in feeding, sleeping, and bodily functions, and have a positive approach to new situations.
- *Difficult* children are negative in mood, often irritable, slow to adapt to change, intense in their reactions, and often irregular in bodily functions, withdraw from new situations, and cry frequently.
- *Slow-to-warm-up* children are slightly negative in mood, initially withdrawing from new stimuli, and have a lower activity level and low intensity of reaction.

Children's temperament is a key area of their social-emotional development and is an important component of their personality that is particularly apparent in infancy and toddlerhood, before children learn to adjust their responses to new and familiar situations and develop ways to verbally communicate how they feel. Temperament types persist, however, as children grow through the preschool and elementary years. Understanding children's temperament types allows families and teachers to support socioemotional and personality development.

Development of the Temperament Model

Chess and Thomas began their research in 1956 with the hypothesis, new at the time, that personality is developed by the interaction of temperament and environment. They conducted a long-term study of 141 children, beginning in infancy and continuing through age 10. The researchers describe the children in the study as being from middle-class families and working-class Puerto Rican families, children with mental disabilities, infants born prematurely, and children with effects of the childhood disease rubella.

In their study of infants and toddlers, the researchers identified nine qualities, or characteristics, that could be clustered into the three basic temperament types, *easy*, *difficult*, and *slow-to-warm-up*, by scoring each of the characteristics on a 3-point scale. Donna Wittmer and other researchers have found similar results in their studies of infant temperament based on aspects of emotionality, activity, and sociability. Thomas, Chess, and Birch also determined that temperament persists as children grow, but is not inflexible in that changes in type do occur. As children develop past infancy, temperament types generally remain the same but are sometimes transformed by environment and experiences.

The nine qualities of temperament are the following:

1. *Activity Level*: the level and extent of motor activity
2. *Rhythmicity*, or degree of regularity, of functions such as eating, elimination, and the cycle of sleeping and wakefulness
3. *Approach/Withdrawal*: the response to a new object or person, in terms of whether the child accepts the new experience or withdraws from it
4. *Adaptability* of behavior to changes in the environment
5. *Threshold of Responsiveness*, or sensitivity, to stimuli
6. *Intensity*, or energy level, of responses
7. *Quality of Mood*: the child's general mood or "disposition," whether cheerful or given to crying, pleasant or cranky, friendly or unfriendly
8. *Distractibility*: the degree of the child's distractibility from what he is doing
9. *Attention Span and Persistence*: the span of the child's attention and his persistence in an activity (Thomas, Chess, & Birch, 1970)

These nine qualities differ for children according to their temperament type, as described by Thomas, Chess, and Birch (1970). Easy children, for example, exhibit a positive approach to people or objects, are

very adaptable in new situations, and experience a low or mild intensity of reaction. Their quality of mood can be described as positive.

In contrast, difficult children demonstrate withdrawal from new people or objects, they adapt slowly to new situations, and their reactions are intense. Their quality of mood is generally negative.

Slow-to-warm-up children, as their temperament type suggests, initially demonstrate withdrawal from new people or objects before being comfortable with them. Like difficult children, they adapt slowly to new situations, but the intensity of their reactions is mild, more similar to that of easy children. The quality of mood among these children is slightly negative.

From their long-term study of temperament types, Thomas, Chess, and Birch (1970) identified what the nine qualities of temperament may look like in children from infancy through age 10. They have provided examples of *activity level* and *adaptability* at six age levels, from 2 months to 10 years. The behaviors of children at 2 months, 2 years, and 5 years serve to illustrate high and low levels of activity. A 2-month-old with a high activity level may wiggle during diaper changes and move about during sleep. With a low activity level, the child is likely to lie quietly during diaper changes and sleep without moving. A highly active 2-year-old engages in active play and may climb on furniture during the day time and out of bed at naptime or at night. A low-activity 2-year-old may prefer quiet play with manipulative toys such as small blocks or puzzles and is likely to stay in bed during naptime. Highly active 5-year-olds are on the move, often running and not staying in one place for long. A 5-year-old with a low activity level is content to sit quietly during long car rides and will usually be able to sit still at the table during mealtimes at home. Teachers can recognize similar high- and low-activity behaviors among the children in their classrooms.

Implications for Practitioners and Parents

Chess, Thomas, and Birch wrote to inform families as well as researchers and practitioners. Their book, *Your Child Is a Person*, first published in 1965, was geared toward parents and communicates the

importance of observing, recognizing, and responding to the individuality of each child. Parenting and caregiving styles in relation to children's temperament have implications for children later in home and school. Appropriate support for children's temperament and the ways in which they respond to the world contributes to their social-emotional development.

The concept of goodness of fit describes the interaction between children and adults in terms of a match or mismatch in expectations and personalities. An outgoing, sociable, and energetic adult may not understand the discomfort of the *slow-to-warm-up* child to a new social experience or the intense negative reactions of a *difficult* child.

Lacking the responsive playfulness of the easy child, unless there is understanding on the part of families, the difficult child may not receive the warmth, positive attention, and nurturing that an infant needs, and may be punished by frustrated and bewildered parents. Parents of slow-to-warm-up children will need to adapt the family's schedules and activities to allow them time to adjust to new people and situations. A possible complication for easy children as they grow is the possibility that, having fit so easily in their families' expectations and standards, encountering differences in settings away from home may be a challenge.

T. Berry Brazelton offers useful advice and guidance for children in the first 3 years of life in the 2006 edition of his book *Touchpoints: Your Child's Emotional and Behavioral Development—Birth to Age 3*. Brazelton's recommendation is for parents to use Chess and Thomas's nine qualities to assess their child's temperament in order to know what is normal for their child. Parents are then able to support the child in new and unfamiliar situations. They will be able to determine if something may be happening that is unusually stimulating or frightening, causing differences in their usual behaviors. Also valuable is the awareness that each child in the family is likely to have a different temperament type. Another application of temperament, according to Brazelton, is to identify some of the reasons for children's wakefulness at night. A widespread concern of parents of infants and toddlers, wakefulness may be a response to any of three temperament types.

Further evidence of the sturdiness of the Chess and Thomas model of temperament is a 1990 video by David Donnenfield, J. Ronald Lally, Peter Mangione, and Sheila Signer called *Flexible, Fearful or Feisty: The Temperaments of Infants and Young Children*, whose title is a translation of *easy, slow-to-warm-up, and difficult*. The video is now widely accessible via YouTube and is currently used in early childhood and child development courses and in professional development for those who work with infants and children.

Appropriate responses of parents and caregivers sensitive to temperament types positively affect the social-emotional development of infants, toddlers, and young children as they grow. Similarly, an understanding of each child's temperament type is critical in classroom settings where interactions with teachers and peers will ideally benefit from "goodness of fit."

Possible Limitations in Application

Oversimplification by parents or practitioners may lead to attempts to label children or assign them to a particular type. Not all children fall exclusively and clearly into one of the three types. A consideration of the nine qualities is important in observing and understanding the temperaments of children. In so doing, adults may notice children at times exhibiting responses characteristic of different temperament types in certain day-to-day contexts or even across time.

Questions for Further Consideration

The concept of varying temperaments has a number of connections to other theories on child development. For instance, the extent to which adults support children of varying temperaments in their encounters with the world becomes a factor in Erik Erikson's stage of trust versus mistrust and, to some extent, in later stages.

In their 1970 research report, Chess, Thomas, and Birch describe some diversity among the children in their study and briefly address the topic of temperament and culture in their 1996 book, *Temperament: Theory and Practice*. However, the question of cultural validity can now be investigated

and is more extensively considered. A systematic, in-depth investigation of the diversity of children and families in the United States adds to our understanding of children's temperament and the development of personality. As an example, the challenge for easy children confronting expectations at school that are different from home may occur among children of the dominant culture but is likely to happen more frequently among those from other home cultures, languages, and ethnicities. Additionally, research to validate the findings will provide revised descriptors of the temperament qualities that reflect the contemporary experiences of infants and children and make the model more meaningful to current audiences.

The temperament type model continues to be a robust and enduring part of the knowledge base, valuable to families, practitioners, and researchers. With strongly anecdotal support, there are yet questions about further applications in the global world of babies and young children and their families and in the changing and complex environments in which children are born and in which they grow in their encounters in their worlds.

TEMPERAMENT AND DEVELOPMENT

According to Mary Rothbart's psychobiological model, *temperament* refers to individual differences in reactivity and self-regulation as expressed through affect, activity, and attention. These differences emerge, with maturation, heredity, and experience, interacting in a manner that results in a unique profile of constitutionally based characteristics.

Reactivity refers to individual response patterns to a broad range of stimuli, and with novel stimuli; for instance, avoidance and approach would be considered reactive tendencies. Reactivity-related constructs are often measured in terms of latency, duration, and intensity parameters of motor, affective, and attentional responses. The amount of time it takes for an infant to smile when playing peek-a-boo is an example of a latency measure of reactivity. In the case of emotional reactivity, behavioral observations often prove to be useful measures. For example, as fear is generally associated with manifestations of distress, freezing, and behavioral inhibition (i.e., latency to engage or immediate retreat from stimuli) and positive affectivity with a rapid behavioral approach toward potentially rewarding stimuli, these behavioral markers can serve as indicators of the two temperament dimensions, respectively.

Self-regulation refers to functions that modulate reactivity. Effortful control, enabling voluntary modification of a reactive response, represents an example of a regulatory temperament construct. Linked with conscientiousness in adulthood, effortful control is critical to development in multiple areas, as diverse as school readiness and theory of mind. Similarly, orienting is considered to be an attention-based regulatory domain of temperament, as orienting can be utilized to modulate reactivity as early as the first year of life (e.g., orienting away from a distressing stimulus). This early appearing self-regulation is captured by parent report via

multiple scales with the Infant Behavior Questionnaire (IBQ-R), developed by Maria Gartstein and Rothbart, wherein these cluster into the regulatory capacity/orienting overarching temperament factors.

Conceptualization and measurement of temperament are largely dependent on the theory being applied. In the case of the psychobiological model, measures include questionnaires for caregivers with items addressing the frequency of specific child behaviors anchored in typical daily activity contexts, as well as laboratory-based observations, wherein episodes designed to elicit specific emotional reactions or regulation efforts are administered in a structured manner. Naturalistic observations have been utilized as well, although not as extensively, and there are also many examples of physiological indices (e.g., electroencephalogram) being utilized to measure aspects of temperament. Although all of these approaches have their own strengths and weaknesses, parent-report measures have the advantage of capturing aspects of temperament that are not readily observable in episodic or laboratory settings and are comparatively simple and inexpensive to administer.

The Structure of Temperament

The psychobiological model of temperament is constructed as a hierarchical system, insofar as there are overarching factors of surgency/extraversion, negative emotionality, and orienting capacity/effortful control, which are composed of more fine-grained dimensions. Surgency is defined by approach behavior and positive affective states, whereas negative emotionality is characterized by behavioral inhibition (hesitation to approach new/unfamiliar stimuli) and a tendency to react with distress, and orienting capacity/effortful control represent regulatory constructs, moderating the influence of other reactive temperament components. These overarching factors remain relatively stable, in that although the more fine-grained dimensions change with development (e.g., inhibitory control is introduced at the toddler level, as infants do not yet present with this capacity to inhibit a prepotent response in producing a novel,

more adaptive one), the broad factors have been shown to remain relatively stable.

Negative Emotionality

Negative emotionality is often considered to be the temperamental equivalent of the neuroticism construct discussed in adult personality literature. Negative emotionality represents tendencies to experience and display fear, anger, sadness, and physical discomfort. In infancy, this factor is identified by expressions of fear, frustration or irritability, sadness, and falling reactivity (defined as the infants' ability to lower his or her own level of distress), which is associated with a negative loading, reflecting a negative associating with distress dimensions, indicative of a regulatory function. Later in childhood, negative emotionality is further defined by shyness, resistance to control, soothability, and discomfort. Resistance to control captures an individual's tendency to reject imposed rules or regulations, and discomfort in this context refers to the child's negative affective response to various sensory information (e.g., brightness of colors or lights, volume of sounds). Soothability (ability to calm with parental interventions), also a regulatory dimension of temperament, loads negatively onto this factor after the first year of life, in a manner similar to falling reactivity.

Negative emotionality is the first domain of temperament to emerge, and aspects of negative emotionality have been measured by Rothbart and demonstrated to be relatively stable by 1 month of age. In laboratory research by Gartstein and colleagues, developmental changes in negative emotionality in infancy have been noted (e.g., with fearfulness increasing over the first year of life), with stability generally observed by the toddler period. Rothbart also described stability between childhood negative emotionality and neuroticism in adulthood.

Negative emotionality is the factor most closely aligned with what Alexander Thomas and Stella Chess (1977) identified as "difficult" temperament. That is, Thomas and Chess defined difficult temperament as a poor adjustment to change; irregular sleeping, eating, and elimination cycles; and

negative response to new stimuli (e.g., using tantrums to express frustration). Importantly, both negative emotionality and difficult temperament have been linked with behavior problems and adjustment difficulties later in childhood and adulthood, recently by Murray Weeks and colleagues.

Surgency

Surgency is a term often used to designate emotional/behavioral tendencies linked with extraversion, manifested in the first year of life. In infancy, researchers tend to measure smiling and laughter, vocal reactivity, high-intensity pleasure seeking, activity level, perceptual sensitivity, and approach (excitement and positive anticipation of pleasurable activities). As would be expected, smiling and laughter are measured in terms of frequency of the target behavior, duration, and intensity. Vocal reactivity is quantified through report of nondistress vocalizations during play and daily activities. High-intensity pleasure refers to a positive response to high-stimulus novelty, complexity, incongruity, and rate, whereas perceptual sensitivity is operationalized as detection of low-intensity stimuli from the external environment. Sociability emerges as an additional dimension in the toddler period and is both linked with other facets of surgency and more consistent with an adult version of extraversion.

Positive emotionality, initially displayed through smiling and laughter by the third month, continues to develop throughout the first year of life, as demonstrated via home observations, parent reports, and laboratory tasks, for example, by Grazyna Kochanska, Katherine Coy, Terri Tjebkes, and Susan Husarek. Positive emotionality becomes increasingly stable in early childhood, with most positive emotions discernible by toddlerhood. It is not surprising that positive emotionality has been conceptualized as a developmental precursor to the adult personality construct of extraversion.

Surgency can result in increased risk or protection with respect to behavior problems/symptoms of psychopathology depending on the context. Gartstein, Samuel Putnam, and Rothbart conducted a longitudinal study of temperament, examining its

associations with internalizing and externalizing difficulties. Replicating the results of previous studies, elevations in surgency were predictive of externalizing behaviors (e.g., impulsivity). Whereas higher levels of surgency are sometimes shown to be protective with respect to the development of depression in older children, concurrent elevations in surgency and negative emotionality in infancy were linked with an elevated risk for internalizing behaviors in later development.

Regulatory Capacity/Orienting and Effortful Control

Regulatory capacity/orienting is a temperament construct unique to infancy and reflects the origins of attention-based self-regulation. This broad factor is characterized by low-intensity pleasure, cuddliness, high soothability, and duration of orienting or attending. Unlike high-intensity pleasure, low-intensity pleasure refers to positive responses to stimuli that are familiar, simple, and low in frequency. Cuddliness is identified through an infant's enjoyment and molding of their bodies to be held by a caregiver, and duration of orienting is an infant measure of attentional persistence, or an ability to attend to a given stimulus over time.

Aspects of effortful control appear to "come online" around the end of the first year of life, and this overarching temperament factor can be successfully measured by asking parents relevant questions in the toddler period. A variety of observation tasks have also been developed to address this regulatory component of temperament and described by Jessica Kraybill and Martha Ann Bell, and a number of these involve conflict (e.g., saying "day" to a picture of the night sky), resolution of which is supported by effortful control. Composed of inhibitory control, attentional focus, persistence, low-intensity pleasure seeking, and perceptual sensitivity, the emergence of this factor is supported by the rapid development of the frontal lobe and other executive functions. With respect to adult personality, according to Rothbart, attributes most closely aligned with childhood effortful control have to do with conscientiousness, which tends to increase over the life span.

The development of effortful control coincides with the emergence of intentional behavioral regulation, which is critical in adaptive functioning. That is to say, a capacity for effortful control allows for individual differences in modulation of more dominant responses in favor of more useful subdominant response, thus facilitating behavioral and emotional regulation. As noted by Rothbart, the development of this set of attributes is particularly rapid between 3 and 7 years of age, and in school-age children, substrates of effortful control (i.e., attentional control) were associated with learning proficiency. Whereas higher levels of effortful control have been demonstrated to be protective, low levels of effortful control function as risk factors. Nancy Eisenberg and her colleagues in a series of studies demonstrated that low levels of effortful control, particularly attentional control, were associated with an increased risk of externalizing difficulties.

Further Developmental Considerations

Though temperament attributes are generally viewed as stable, greater variability prior to the emergence of effortful control has been noted. This change is largely understood in terms of executive functions developing and modulating the expression of temperament reactivity, leading to increased stability of these attributes. Beyond these neurobiological influences, it is important to note that temperament is viewed as open to environmental influences, contributing to differences over time. For example, temperament in infancy appears to be shaped in part by the actions of others that are likely culturally bound, resulting in considerable differences in temperament development across cultures, identified in research by Gartstein and colleagues.

Differential continuity of temperament attributes is understood in terms of homotypic continuity, which is the consistency of similar behavioral/emotional tendencies over time, as well as heterotypic continuity, wherein seemingly different expressions of temperament reflect a common underlying aspect of individual differences. According to Jerome Kagan, homotypic continuity is most evident after

puberty, whereas earlier childhood is more likely to be heterotypic. That is to say, behavioral/emotional expression changes with development in a more salient manner in early childhood, primarily as a result of an overall rapid pace of development during this period, despite continuity in underlying factors/neurobehavioral systems. For example, Kagan, Nancy Snidman, and Doreen Arcus (1998) reported that negative reactions to novel stimuli at 4 months of age were associated with avoidance of peer interaction at 4 years. In both instances, facets of negative emotionality are being expressed, but the behavior varies in accordance with maturity and changes in the environment.

Direction of Future Research

Important advances have been made with respect to temperament measurement, identification of the structure of temperament, and its developmental trajectories. Temperament continues to be a very active area of research within developmental science and the study of individual differences. In addition, more recent work, for example, a study by Tim Oberlander and colleagues, has begun to examine genetic and epigenetic foundations of these individual differences, as well as other biological factors, contributing to prenatal influences, often referred to as “fetal programming.” Future studies are likely to uncover important connections between fetal exposure to maternal stress and nutrition, and the underlying biological mechanisms linking these fetal programming effects to temperament development. In addition, temperament has become increasingly important to mental health, as it has been shown to moderate treatment efficacy, along with being an important etiological contributor. Thus, research that examines temperament in the context of prevention/intervention efforts is likely to expand. This is an exciting period for the study of temperament, as the gleaned insights are being implemented across a variety of areas in both basic science and applied/service efforts.

THEATER

Theater in the early childhood years can be understood as a developmental process, and as a unique, creative expression of lived experience—and of future possibilities. Theater takes many forms in early childhood: imitation and deferred imitation, and symbolic or imaginative play.

What accounts for performance in early childhood? Jean Piaget argued that children construct understanding of their world through action (1929/2007, 1936/1963, 1937/1954). Qualitative changes in cognitive understanding are accompanied by changes in how children perform their evolving comprehension. They perform their understandings of how the world works through acting upon and in interaction with their environment. As they grow, how children understand the world and how they perform these understandings undergo qualitative changes. Children's activity is geared toward creating comprehensive understanding of the world—physical and social. This entry addresses children's developing understanding of the social environment, and its connections to theater as an arts discipline and as an everyday early childhood activity.

Theater is represented by children's performative understanding of their social environment as characterized by interactions with others and the everyday drama of human activity, as well as by human need, emotions, and agency. Lev Vygotsky (1962, 2004) theorized that the child's environment is first and foremost social and that what children learn and what they subsequently enact are rooted in the particular cultural surroundings in which they live. Like Piaget, who identified the infant's capacity to imitate observed actions—and especially to delay imitation (deferred imitation)—Vygotsky focused on the here and now of children's environments and on the matrix of actions and interactions that children observe. Although

Vygotsky was no stranger to the concept of the inner life and wrote widely on creativity and the imagination, he tilted toward lived experience as a touchstone for both cognitive and affective development, rather than toward an inner life ruled by wishes and fantasy. The imagination, Vygotsky (2004) posited, was grounded in the real world of children's lived experience, rather than an expression of the inner life, as his contemporary, Sigmund Freud, maintained.

Taking a developmental approach, play is the theater of early childhood. Imitation or miming of actions observed in real time is followed by deferred imitation. The child's gesture represents a fragment of observed experience. Children perform observed social interactions; the act of performance—and especially repeat performance—serves to incorporate gestures, expressions, and modes of interaction into their repertoire of lived social experience. Social knowledge in the early years emerges through close observing and incorporating gesture and relational modes of interacting. Performance is transformative: The child's early imitative gestures transform other people's actions, affective expressions, and patterns of interacting into the child's own social repertoire. Whose social repertoire, though, is performed and becomes the child's?

Theater in early childhood develops out of a matrix of emotional or affective relationships with loved attachment figures. Attachment provides motivation for incorporating and performing observed actions, emotional expressions, and interactive patterns in early childhood. It facilitates joint attention (Korn-Bursztyn, 2012), a key process that leads children out of closed dyadic relationships into wider social and cultural environments and networks of relationships. The phenomenon of joint attention between children and responsive, trustworthy adults draws on attachment patterns but focuses on something outside of the closed dyadic system. Joint attention assumes a third thing, something external to the dyadic relationships, but in which both parties invest shared attention. The third thing in childhood is typically play—enactment—and often embellishment: of lived experience and also of imagined, possible experiences and worlds.

When children engage with others in play, they experience a sharing of attention and focus, resulting in meaningful experience. Theater, the performance of lived experience and future possibilities, gives rise to a third thing—meaningful experience that is rooted in social interaction. Meaningful experience arises out of the interaction between lived experience, future possibility, and meaning making with others. The social component of shared meaningful experience is significant to children's play with others. In play, children engage in joint attention with their peers—sharing of attention and positive, enjoyable affective experience create bonds between children. This process is similar to how children and their caregivers bond with each other in early attachment relationships. Joint attention, especially when accompanied by positive emotions, enhances bonding between parent and child in the early years. Joint attention also functions to enhance and promote attachment relationships postinfancy. Children who perform or play their social knowledge with others—with other children, caregivers, teachers, and therapists—develop stronger emotional ties, or attachments, to these figures.

Theater in early childhood begins with performance of observed interactions but quickly develops two streams: One represents lived experience, and the other, childhood desire and ambition. Theater is enactment of experience, witnessed and lived, while the other stream is associated with childhood desires. In both streams, roles are created, assigned, and inhabited. For example, early dramatic play in toddlers typically consists of enactment of nurturing rituals of feeding and sleeping. In nurturing ministrations, even young toddlers can turn passive into active, enacting both the nurturing acts and the experience of feeling nurtured. Drawing on the social knowledge that attachment relationships have already laid down, toddlers can typically enact both nurturing caregiver and cuddled baby. The preschool-age child may perform elaborate scenes of competence, authority, and power in the guise of teacher, portraying scripts that may include recognizable characterizations but that may also emphasize a childhood fantasy of adultlike competence and control.

Children are serious about their relationship to theater—not surprising given the outsize role it plays in the construction of their social knowledge and social identities. Role assignment is a serious endeavor, as is staging the scene for the drama that is to unfold. The frame is so meaningful that it often takes precedence over narrative content. For young preschool children, the social interactions and knowledge that undergird enactment of stories—their own lived experience, and their own growing linguistic competence—are key. The process of theater—and not the finished product—distinguishes theater in childhood from its adult counterparts.

It demands that adults take a secondary role to children's initiative—theater creates opportunities for agency, offering opportunities for children to create the frame, including the narrative, which the actors will then perform. Theater in childhood is improvisational. It is negotiated; children argue about role assignment and plot development. It can hew closely to lived experience, borrowing from the content of everyday lives, but can also draw directly from cultural artifacts, including books, songs, and rituals. When adults join in children's theatrical productions, they need to be clear, however, that they are joining—taking on assigned roles and developing these in accordance with what they believe the children need, rather than their own desires.

THEORY OF MIND

Theory of mind (ToM) is the ability people have to look beyond observed behavior and to make inferences about unobservable mental states of themselves and others and to understand that (a) others have beliefs, desires, and goals that differ from their own and (b) this knowledge can help interpret, explain, and predict others' behavior (De Bruin & Newen, 2012).

A theory of mind analysis of the fairy tale “Little Red Riding Hood” offers a realistic and remarkable example of what a difference our knowledge about minds makes in how we interpret and understand others. Angeline S. Lillard (1997) used the story of Little Red Riding Hood to show how individuals' understanding about minds differs when they interpret and understand others' minds. Little Red Riding Hood hears from the woodcutter that her grandmother is ill. She wishes to help her grandmother recover (she is considerate and caring). Little Red Riding Hood believes that a basket of treats can improve her grandmother's health; therefore, she carries the basket of treats through the woods to her grandmother's house (beliefs and desires guide her deeds). When she reaches her grandmother's residence, she finds that the wolf is in her grandmother's bed; however, she falsely infers that the wolf is her grandmother (appearances can be deceptive). After she recognizes that it is a wolf, she becomes terrified and runs away because she realizes that wolves can harm people. The wolf, who actually desires to eat her, jumps out of the bed, runs after her, and tries

to capture her (Lillard, 1997). This example shows that the individuals' mental states in theory of mind cause them to be more sensible, foreseeable, and alluring. Individuals rely on their abstract mental state understanding to both interpret and validate the others' behavior, like any theory that is used to describe and predict related circumstances (Sabbagh, Benson, & Kuhlmeier, 2013; Tomasello, 2009).

Studies on young children's knowledge about the mental world have concentrated on their interpretation of mental states and whether their mental representations of the state of affairs conflicts with reality (Lockl & Wolfgang, 2007). David Premack and Guy Woodruff's (1978) study introduced this realm of research and established the phrase “theory of mind,” in which the preliminary research hypothesis was that apes, like humans, have a theory of mind. Based on Premack and Woodruff's study, Heinz Wimmer and Josef Perner (1983) developed an assessment to determine children's theory of mind and called it a *false-belief task*, which assesses individuals' ability to infer that others hold beliefs that differ from the (perceived) state of the world (Goodman et al., 2006). This assessment is widely used, because it shows that individuals believe things that are not true. False-belief understanding is typically assessed based on standard tasks (Atance, Bernstein, & Meltzoff, 2010) that require children to predict and explain their interpretations or acts of someone whose beliefs about the world are mistaken. The following is Lillard's (1998) description of Wimmer and Perner's (1983) original false-belief task:

Children are shown a doll [Maxi], who hides a piece of chocolate in a blue cupboard. Then Maxi leaves the scene. During his absence, his mother arrives, moves the chocolate from the blue cupboard to a white one, then also leaves. Maxi returns. The chocolate is not visible as both cupboards are closed, and Maxi has clearly not seen his mother move the chocolate. Children are asked, “Where will Maxi look for his chocolate?” One should say, “The blue cupboard” since that is where Maxi left the chocolate, and he has no way of knowing that it has been moved. But what Wimmer and Perner found is that children

under four years of age tend to fail the test by claiming that Maxi will go to the white cupboard, where his mother put it. (pp. 11–12)

Studies on theory of mind have traditionally used false-belief reasoning with 3- to 5-year-olds. Presently, researchers assumed that younger children's theory of mind can be determined and have modified the false-belief tasks to use with younger children (Birch & Bloom, 2007) including infants (Apperly, 2012). Researchers designed developmentally appropriate adaptations of Wimmer and Perner's false-belief tasks to support that theory of mind can be determined in children who are younger than 3 years old. They found these developmentally appropriate false-belief tasks to be successful with younger children. Several researchers (e.g., Baillargeon, Scott, & He, 2010; De Bruin & Newen, 2012; Onishi & Baillargeon, 2005) adapted the false-beliefs task to use with infants. They applied spontaneous-response tasks (De Bruin & Newen, 2012), nonverbal tasks (Onishi & Baillargeon, 2005), and computer monitor tasks (De Bruin & Newen, 2012) to validate that false-belief understanding develops before 3 years of age. Those researchers who used spontaneous-response tasks show that children develop this aptitude before 3 years of age (He, Bolz, & Baillargeon, 2011). They discovered that performance on the false-belief task is a developmental process.

Although false-belief tasks have been used for more than 3 decades, research on several aspects of false-belief tasks must be conducted to contribute to the knowledge of the theory of mind. For instance, studies need to identify ways (a) to interpret the rationale for the content and attitudes in these tasks, (b) to improve the inferred assessment in various situations and individuals, and (c) to apply a broader analysis of the mental state components. These suggestions offer important guidelines for future research (Goodman et al., 2006) in theory of mind. Also, the development of understanding of motivational states should scientifically examine the children's theory of mind knowledge and the situations in which it is developed (Astington, 2001).

THEORY TO PRACTICE IN EARLY CHILDHOOD EDUCATION AND CARE

In order to consider what we mean by “theory to practice,” we must first consider what a theory is, whether there is any agreement among scholars about this, and what purpose theories serve. There are those who would make a series of observations about a phenomenon, string them together, draw some relationships among these observations, and then call it a “theory.” There are others who equate “theory” with “truth.” Neither of these definitions is what we have in mind as we try to explicate the process of putting theory into practice. Rather, we see theory as the lens that one uses to view a particular phenomenon, in this case early childhood education and care (ECEC). This lens is constructed through careful, empirical observations that help us construct a framework that hangs together with logic. R. Murray Thomas suggests that theories go through four phases of development before becoming accepted as theories: foundations/convictions, model descriptions, logical deductions, and conclusions. A theory must also be able to be evaluated for soundness and stand up to scrutiny by others.

Evaluating the Utility of Theories

According to Thomas, there are good theories and bad theories. He posits fourteen standards to examine the utility of the theory for application to the real world of children and families. Consequently, he urges us to look at a theory's explanatory value, its clarity, its ability to predict future occurrences, whether it offers guidance to others, whether we can test it to either confirm or deny its plausibility, whether it continues to draw interest, whether it can be expanded, whether it answers our questions about children and families, and finally whether it satisfies our need to understand what we observe. If this defines *theory*, then how do we go about putting it into practice?

Reciprocal Relationship Between Theory and Practice

Theories of child development have traditionally provided a foundation for pedagogy in early childhood education and early intervention. Although a myriad of theories exist within the scholarly domain of human development, contemporary psychologists have no consensual understanding of what constitutes a theory or how theory should be used, revised, and appraised. Although theory is often portrayed in research as static, many scholar-practitioners (e.g., Thomas as mentioned previously) contend that theory must operate as an essential tool in knowledge making and take theory to be an emergent form whose life demands focused chronicling, analysis, and care. A dynamic perspective encourages scholar-practitioners to explore how a theory travels, is taken up in different times and places, and changes. It is this dynamic view of theory and its reciprocal relationship to practice that informs contemporary practice in early childhood education.

This notion of continual reciprocal negotiation between theory and practice was well framed by Edward Said, who argued that the context of time and place in which a theory is developed is essential to understand as we consider the usefulness and appropriateness of a theory. He suggests that we need to consider these contexts as we apply theory in future contexts.

The reciprocal and dynamic nature of theory is exemplified in the evolution of the Reggio Emilio model. Loris Malaguzzi developed his theory and philosophy of early childhood from direct practice with young children over a 30-year period—asserting the position that practice drives theory. Many contemporary scholars contend that Malaguzzi was heavily influenced by a social-constructivist framework derived from the theories of John Dewey, Jean Piaget, Lev Vygotsky, Jerome Bruner, and others, and that their influence, particularly that of Dewey's, are clearly visible in the Reggio Emilio classrooms.

So then, what is the relationship between a conceptual model, such as social-constructivism, and a theory that informs and is validated through practice? Typically, models are construed as being elements of paradigms that operate to build theories that can then be validated through practice. Thus, the reciprocity that is clearly evident in models of early childhood pedagogy such as Reggio Emilio, Montessori, culturally adapted models, inclusive models, and even response to intervention models all inform contemporary practice as well as are continually refined and adapted through implementation and practice across time, geography, culture, and population.

Concept of Unified Theory

Early childhood education has moved from a set of practices based on a single theoretical perspective (e.g., constructivism, behaviorism) to a *theory of practice*, often also referred to as a *theory of change*, or *unified theory*. Jack Shonkoff posits that if early childhood policy and practice focused more explicit attention on buffering young children from the neurodevelopmental consequences of toxic stress, then scientists, practitioners, and policy makers could work together to design and test creative new interventions that combine cognitive-linguistic stimulation with protective interactions that mitigate the harmful effects of significant adversity, beginning as early as possible and continuing throughout preschool. For this two-pronged approach to succeed, new strategies will be needed to strengthen the capacities of parents and providers

of early care and education (beyond the provision of additional information and supports) to help young children cope with stress.

Relationship Between Theory and Policy?

ECEC has become a policy priority in many countries. A growing body of research recognizes that ECEC brings a wide range of benefits, including social and economic benefits; better child well-being and learning outcomes; more equitable outcomes and reduction of poverty; increased intergenerational social mobility; higher female labor market participation and gender equality; increased fertility rates; and better social and economic development for society at large. The Organisation for Economic Co-operation and Development (OECD) has developed what it terms a “Quality Toolbox for ECEC” that aims to define *quality* and outlines five policy “levers” that can enhance it in ECEC. Policy analysts describe policies metaphorically as levers that can be tripped to change the behaviors of individuals and groups. These five levers include setting out quality goals and regulations; designing and implementing curriculum; improving workforce conditions; qualifications and training; engaging families and communities; and advancing data collection, research, and monitoring. The toolbox is intended to impel improvements in ECEC in participating countries and offers country by country profiles on selected themes. In each report, the focus is on the alignment of the selected lever—workforce conditions and qualifications, for example—and how this contributes to improved child development.

Poverty is a clear contributor to school failure, so there has been considerable research on the impact of high-quality early childhood education and care. Longitudinal studies such as the HighScope Perry Preschool Study, the Abecedarian Project study, and the Chicago Child-Parent Centers study provide strong, robust evidence of the lasting effects of high-quality preschool programs on young children living in poverty. The continuing struggle is how to take the evidence on quality early childhood education and care and put it into

large-scale practice. In the United States, the Common Core State Standards have worked their way down to early childhood education in prekindergarten classrooms in many states focusing on “developing the whole child” through play, artistic expression, teaching compassion, and cognitive development. The other states that have not embraced the Common Core standards—for example, Alaska, Nebraska, Texas, and Virginia (and more states are joining these ranks)—all reflect similar emphasis as those outlined by the Common Core.

Given that quality early childhood education and care is not aligned with any single theory of child development, best practice is defined by continued research on the outcomes associated with the two-pronged approach described by Shonkoff and others. This approach involves a focus on prevention of the known effects of poverty and other associated contributors of toxic stress in children while providing a coherent theoretical framework for scaffolded experiences in purposeful play and the social interaction and emotional regulation that both reciprocally contribute to it and develop from it.

Examples of Theory-Practice-Policy Links

Urie Bronfenbrenner’s ecological theory as it influences practice in ECEC is a good example of taking Shonkoff’s suggested two-pronged

approach and the reciprocal nature of theory to practice. It emphasizes factors within the immediate setting (e.g., home, classroom, the role of adults), the interrelating influences of different settings in which a child participates (e.g., communication between parents and teachers), and the influences of the broader ecology (e.g., government policies, cultural values). *Unified theory*, as applied to ECEC by Samuel Odom and Mark Wolery, rests on the fundamental tenets of families and homes as the primary nurturing contexts, thereby resulting in the design of evidence-based practices (EBP) to support building relationships as an essential feature. It is founded on the belief that children learn through acting on and observing their environment, hence impelling the development of EBPs that teach educators how to mediate children’s experiences to promote learning. The fundamental belief of *unified theory* that families and programs are influenced by the broader context has impelled the development of family-centered planning, and the design of culturally responsive programs. Figure 1 presents a logic model for explicating the relationship between theory and practice.

The development of a theory (the lightbulb) begins with a negotiation among the parts of an interactive model composed of observations, axioms, and beliefs that explain a phenomenon. We test the theory by applying it and then examine the

Figure 1 Model of Theory-to-Practice Relationship

evidence of these practices to see if the theory is confirmed or is in need of revision. The arrows in the figure represent the reciprocal nature of the process.

Conclusion

The search for a definition of *theory* and examination of the necessity for evaluating the utility of the theory moves us into an exploration of the relationship between theory and practice and the reciprocal influence of these constructs. The logical next step is to use our understanding of theory to develop models of practice, continuing to assess the utility of the models and revise them to improve their utility. The results of such scrutiny and continual refinement should lead to a path of influencing policy that affects young children and families. At this point, the logic model begins to loop back as changes in policy influence practice and impel research on the impact of policy. Thus, we are feeding our findings back into the loop, reciprocally modifying models and theories. It is this continuous looping that defines the dynamic relationship and iterative process between theory and practice.

THINKING

The terms *thinking* and *cognition* are sometimes used interchangeably, yet they have slightly different meanings. *Cognition* is the broader term signifying

general mental operations, such as recognizing patterns, processing language, and remembering. Thinking, on the other hand, is just one aspect of cognition and is defined as the process of using one's mind to reason or to produce thoughts. Thinking is used in various ways—to solve problems, make decisions, organize and synthesize information, develop plans, form judgments, and create new ideas.

This entry provides a brief overview of what research and theory have to offer to current understandings about young children's thinking. This entry also offers insight into how research on the thinking of young children provides strong support for what has been defined as developmentally appropriate practices in early childhood education.

Educational Research and Theory

At one time, prior to the 1900s, little was known about how young children think. The generally accepted understanding was that young children had less knowledge to work with than older children and adults, but that the difference in thinking was more in terms of quantity rather than quality. More recent research indicates that young children not only have less knowledge (facts) than older children and adults; they also use the knowledge they do have in different ways.

Jean Piaget and Cognitive Development

One of the first psychologists to systematically study the cognitive development of children and the way they think was Jean Piaget. Findings from Piaget's research, which was conducted in the early to mid-1900s, are still used to guide educational practices for young children. The following understandings based on Piagetian research and theory are reflected in "developmentally appropriate practices" developed by the National Association for the Education of Young Children (NAEYC).

- Children construct their own knowledge about the world around them. They learn by doing and actively exploring.
- Children's ability to think evolves over time and moves from simple to higher (or more complex) levels.

- Both biological maturation and environmental experiences influence how children's thinking develops over time.
- The way children think is qualitatively different than the way older children and adults think.

Piaget identified four distinct stages of cognitive development during childhood. Each stage is defined or characterized by a different way of thinking, as follows:

1. Sensorimotor stage—Thinking at this stage is characterized or demonstrated by motor activity.
2. Preoperational stage—Thinking is reflected through language, the use of symbols, and imaginative expressions. Thinking at this stage, however, is still nonlogical and nonreversible. Reversible, according to Piaget, refers to mental or physical actions that can go back and forth. An example of reversible thinking includes understanding that if $1 + 2 = 3$, then $3 - 2 = 1$. Another example is understanding that if ice melts and becomes liquid, it can be frozen again and become a solid.
3. Concrete operational stage—Thinking is demonstrated through logical and systematic manipulation of symbols related to *concrete* objects. At this stage of thinking, it is understood that some mental and physical actions can be reversible.
4. Formal operational stage—Thinking is demonstrated through the logical use of symbols related to *abstract* concepts.

Bloom's Taxonomy

Another educational psychologist studying the way young children think was Benjamin Bloom. His major contribution to educational research is often referred to as "Bloom's Taxonomy." This taxonomy, or framework, outlines six increasingly complex levels of thinking which are divided into lower levels and higher levels of thinking. The three lower levels consist of (1) knowledge, (2) comprehension, and (3) application. The three higher levels are (1) analysis, (2) synthesis, and (3) evaluation.

Bloom's original taxonomy was recently revised by a group of cognitive psychologists and others working to make this framework more applicable to instructional planning, where the goal is to help students move from the lower levels to the higher levels of thinking. Following is a brief description of what each level of thinking entails according to Bloom's revised taxonomy. They are presented in the order of lower levels to higher levels of thinking.

Remembering—recalling information

Understanding—explaining ideas or concepts

Applying—using information in another familiar situation

Analyzing—separating information or concepts into parts to explore understandings

Evaluating—justifying a decision or making a judgment about the value of a concept or idea

Creating—generating new ideas

Teachers, including early childhood educators, are encouraged to plan instruction in a way that will help students move from lower to higher levels of thinking. This idea is sometimes expressed as moving students beyond rote-and-remember learning to deeper levels of thinking. Foundational knowledge is accepted as a starting point for instruction but teaching practices and learning experiences are intentionally designed with higher order thinking in mind. The goal of this instructional approach is to help students move from remembering to understanding to applying, to analyzing, and finally to creating. As the following selected statements from a position paper developed by the National Association for the Education of Young Children show, there is strong support for using this instructional approach when working with young children.

- Developmentally appropriate practice does not mean making things easier for children. Rather, it means ensuring that goals and experiences are suited to their learning and development and challenging enough to promote their progress and interest.
- Effective, developmentally appropriate curriculum is based on what is known about the interrelationships and sequences of ideas, so that children's later abilities and understandings can be built on those already acquired.
- Development and learning advance when children are challenged to achieve at a level just beyond their current mastery, and also when they have many opportunities to practice newly acquired skills.
- To adjust the complexity and challenge of activities to suit children's level of skill and knowledge, teachers increase the challenge as children gain competence and understanding.

Gardner's Theory of Multiple Intelligences

The focus of some recent research is on how the brain influences specific functions. Some researchers, for example, are using information processing theory to understand memory. Others are studying ways in which intelligence is manifested and how it differs from individual to individual. One outcome of this line of research is Howard Gardner's theory of multiple intelligences. In 1983, Gardner proposed seven different intelligences: (1) linguistic, (2) logical-mathematical, (3) spatial, (4) musical, (5) bodily-kinesthetic, (6) interpersonal, and (7) intrapersonal intelligence. Gardner has since added naturalistic intelligence as an eighth intelligence. According to Gardner, these different intelligences—or ways of knowing the world—are present in every individual but differ in extent from one person to another.

Gardner's theory challenges traditional understandings about human intelligence and the way students' thinking can be assessed. The traditional theory of intelligence is based on the assumption that human cognition is unitary and that individuals have a single, quantifiable intelligence. Gardner's theory indicates that intelligence is not a static structure that can be effectively measured and quantified. Gardner presents intelligence as a multifaceted system that can be developed throughout an individual's life. The theory of multiple intelligences is a useful framework for developing educational programs where the individual needs and

strengths of each child are understood and respected. This approach reflects the principle of individual appropriateness as articulated in developmentally appropriate practices.

Lev Vygotsky and Anti-Bias Education

The content of what children think about extends far beyond academics and what they experience in the classroom. Research indicates that culture plays a major role in what and how children think. Some researchers, including Lev Vygotsky, worked from the premise that individual development can't be understood without considering the social and cultural context within which it is embedded. According to Vygotsky, social interaction plays a fundamental role in the development of cognition; and social interaction always occurs within a cultural context. Vygotsky also believed that the community in which children live plays a central role in how they "make meaning" and construct knowledge about themselves and the world around them.

Vygotsky's theory is sometimes referred to as *social development theory* and includes the idea that how children think about themselves and the social group to which they belong is an integral part of their overall development. Biases of the larger society, which include racism and sexism, can negatively affect a child's self-awareness, confidence, family pride, and social identities. Anti-bias education, which is designed to combat the harm such biases have on children, presents a positive way to think about diversity and equity among children. Surrounding children with positive messages about human diversity, giving them accurate language for human differences, and helping them develop a positive image about themselves and their social group are all critical components of an anti-bias education.

Anti-bias concepts are included in the developmentally appropriate practices (DAP) developed by the National Association for the Education of Young Children. One of the principles on which DAP is based calls for practices which are individually appropriate. This includes knowing what is culturally important to a child and his or her family and then planning activities and providing

experiences consistent with the cultural values and practices of the community in which the child lives.

Brain Research

While how children think and how their brains develop aren't exactly the same thing, these two areas of research are certainly connected and have similar findings. Both areas of research indicate that what happens in the earliest months and years of a child's life has long-term consequences on later development and learning. Brain research, for example, indicates that early experiences in a child's life help to shape the actual wiring of the human brain. Research on cognitive development indicates something similar—that is, that early stimulation promotes later growth and development, while the lack of stimulation curtails such growth.

Brain research also indicates that children's ability to learn is closely tied to their emotional development and to the quality of relationships in their lives. How well a young child learns, therefore, depends in part on the relationship between that child and the teacher and on the emotional climate the child experiences in and outside the classroom. Productive and creative thinking is more likely to flourish in an environment where children feel safe versus in an environment where children feel intimidated.

Brain Principles

In 2008, brain scientist John Medina wrote *Brain Rules*—a book focusing on how the human brain works. In addition to explaining what scientists already know about the brain, Medina also outlined 12 principles for using the brain to maximize human potential. He called these "brain rules." Since 2011, Medina has published a follow-up book, *Brain Rules for Baby*, in which he applies what scientists know about the brain to what parents (and teachers) can do to support the development of smart and happy children.

Brain Rules and Early Childhood Education

Some work has been done since the publication of *Brain Rules* and *Brain Rules for Babies* to link

brain principles to high-quality early childhood education. A basic premise of this work is that there are numerous benefits to the linking of education, neuroscience, and classroom instruction. Fortunately, what neuroscience suggests for optimizing child development is consistent with what has been articulated in the early childhood field as developmentally appropriate practices. These practices include engaging children in meaningful experiences, encouraging cooperative learning, and providing active learning opportunities. Programs implementing these practices support brain development while also being developmentally appropriate.

TODDLER ROOMS

The term *toddler* is widely used to incorporate the period of early childhood after infancy until age 3. Children under 3 in group care are sometimes separated by age into separate rooms—rooms for infants who “graduate” into rooms designed for 1-year-olds, who transition to rooms for 2-year-olds. Alternatively, toddlers are found in multiage groupings of birth to 3-year-olds. Whatever the configuration, toddler rooms are spaces purposefully planned for the care and education of these very young learners. Toddler rooms are found in full- and part-time care settings including family child care homes, community child care centers, nursery schools, preschool programs, child care ministries, and Early Head Start programs, as well as community programs supporting families and children, such as YMCAs, family resource and literacy centers, and rooms that provide care during religious services in churches, synagogues, and mosques.

High-quality care for toddlers in groups requires specialized expertise from professionals with educational preparation specific to working with children under the age of 3. A specific knowledge base and skill set provides understanding of how to support rapid changes that occur during the first 3 years of life in growth, development, and learning and as it occurs in interaction with very young children's experiences, culture, and family contexts. At the heart of practice with toddlers, as with infants, is attentiveness to relationships with, between, and among their adult child care providers, peers, and families. A requisite to supportive relationships in group care is that adult caregivers have the ability (knowledge and skills) and capacity (dispositions) to engage sensitively and responsively with toddlers as communication partners.

The remainder of this entry presents further information about group care policies, environments, and practices in toddler rooms. Current scholarship concerning toddlers in group care calls for policies and practices that promote strong, trusting relationships and environments that engage them in interesting, meaningful play experiences.

Guiding Principles

Regardless of a program's philosophical model or curriculum, professionals who care for and educate toddlers in groups should base actions on critically examined beliefs, guided by reason and sound ethical and moral principles. Numerous curriculum and program models exist, promoted for toddlers and for birth-to-age-3 group care in general; most have in common principles based upon the importance of relationships, inclusion, and communication. Developmentally appropriate practice (DAP) articulates a philosophical viewpoint and guiding principles around which caregivers can think about how toddlers grow, learn, and develop. Although DAP does not prescribe a model or endorse a particular curriculum for toddlers, it does provide a reflection point for caregivers as they plan, implement, and assess environments, relationships, and experiences with toddlers in their group care settings. DAP articulates seven principles for infant and toddler group care:

1. Understand there are multiple influences on development (e.g., access to health care, literacy level of family members, community resources), and growth and development must be viewed holistically, considering all domains of development simultaneously.
2. Welcome all infants and toddlers and their families regardless of beliefs, circumstances, needs, languages, and communication styles.
3. Enter into full partnership with families in supporting their infants and toddlers, respecting families as partners (i.e., rather than as clients or customers), honoring and respecting the decisions they make about their children.
4. Be culturally responsive by being mindful of all messages conveyed to infants and toddlers in care and the messages conveyed to their families, being respectful toward the families' responses to these messages, and acting deliberately to support every child's sense of self, including family and cultural bonds.
5. Respect infants' and toddlers' rights as full participants by respecting their needs and preferences, allowing choice, and supporting their overall well-being in their current daily lives as well as in preparation for the future.
6. Create and maintain a positive emotional climate, investing in all adult and child relationships with, between, and surrounding infants and toddlers in care.
7. Engage in sensitively responsive care by remaining mindful, in the moment when communicating with infants and toddlers, and responding in a timely fashion to expressed needs and desires.

Caregivers need to be aware of physical and structural considerations shown to be important in toddler rooms. State licensing regulations, which vary from state to state, specify minimum size for toddler rooms, and health and safety recommendations mandate factors such as required spacing between cribs and cots, whether food can be prepared on site or off, records that must be maintained, fire codes, and so forth. Recommendations for group sizes and the ratio of caregiver to toddlers come from the field of early childhood education and have remained fairly consistent in the United States for more than 20 years:

<i>Ratios</i>	<i>Group Sizes</i>
In room with 1- or 2-year-olds (separately): 1 adult: 5 or 6 one-year-olds or two-year-olds	In room with 1- or 2-year-olds (separately): 10 to 12 children with 2 to 3 adults for group size of 12 to 15 total
In multiage room with infants, 1-year-olds, and 2-year-olds: 1 adult: 3 or 4 children	In multiage room with infants, 1-year-olds, and 2-year-olds: 6 to 12 children with 2 to 3 adults for group size of 8 to 15 total

The primary knowledge bases informing practice during the first 3 years come from scholarship that addresses child growth and development, early learning research from education and psychology, and brain development studies. Highly qualified caregivers in toddler rooms utilize strong educational backgrounds and professional development focused on the knowledge appropriate for the field, along with guiding principles of DAP outlined earlier, and in-depth understanding of the unique nature of and changes that occur during the first 3 years of life to create supportive environments, relationships, and experiences for the toddlers in their care.

Understanding Toddlers

Important to understanding toddlers is consideration of changes that occur in three key developmental foci during the period of birth to 3 years—security, exploration, and identity. Each of these needs or challenges is present throughout the first 3 years, changing in intensity of emphasis over time. The concentration of physical and psychological energy shifts as the baby ages from young infancy to mobile infancy and through toddlerhood. Very young infants focus much of their energy on issues of security, whereas mobile infants and young toddlers, still seeking security, are more defined by their focus on exploration. Noticeable in older toddlers is a characteristic shift in focus to seeking to understand the self in the context of other people and things; this focus on identity is done through exploration and in the context of a developed sense of security.

Security

The security toddlers need to be risk takers and problem solvers as they explore the environment is built upon a strong secure base created by the trusting relationships and responsive care provided in infancy. Toddlers need to have learned as infants, and to continue to feel they can trust that their needs will be met in a timely and predictable fashion by a respectful, loving adult. The practice of assigning “primary” or “key” caregivers in both infant and toddler rooms promotes this sense of security. One caregiver becomes principally, but

not exclusively, responsible for a small number of children within the group with the goal of forming a particularly secure attachment relationship with those in that smaller subgroup. Continuous care practices in which groups of infants and toddlers remain together with the same primary caregivers over extended periods of time in birth-to-3 rooms further contributes to a strong sense of security.

Exploration

Mobile infants and young toddlers learn about themselves and the world around them when allowed to utilize all of their senses and move their bodies freely through space as they explore environments and the objects and people within them. Toddler rooms must be organized and equipped with materials that help toddlers experience different and interesting sights, sounds, tastes, textures, and smells; and encourage them to use small and large muscles to grasp, clap, reach, slap, drop, push, pull, bang, roll, and climb, and clamber around, under, over, and through all available surfaces (indoors and outside). Sufficiently interesting materials and toys should be available that challenge, yet do not frustrate, and facilitate the development of the understanding of basic concepts such as object permanence, patterns, and cause and effect.

Identity

Older toddlers, while still seeking security and learning about the world through exploration, are focused on building a sense of identity, of understanding who they are in relation to other people and objects in the world around them. Most important is making sure toddlers develop and maintain a healthy sense of self in terms of feeling they and their families are valued and respected. Children under the age of 3 learn important messages about caring for others and that they themselves are persons worthy of care by the way they are cared for in the group care setting.

Supporting Development and Learning

Specialized knowledge, skills, and dispositions are needed for the group care provider to support the

needs, interests, capabilities, and developmental achievements of each toddler in the room, all occurring at varying rates and demonstrated within multiple domains. Specifically, the professional caregiver of toddlers must focus simultaneously on supporting each of the highly interrelated areas of development discussed in this section: social-emotional development, critical thinking skills, physical skills development, the development of personal care and self-help skills, and the development of communication and literacy skills.

Social-Emotional Development

Central to the toddler room caregiver's focus is to help ensure toddlers' emotional well-being each and every day, while supporting their overall healthy social-emotional development. Toddler room caregivers who plan well provide toddlers opportunities to take on roles within the group to develop a sense of belonging and responsibility and experiences to develop and practice prosocial behaviors that promote caring for and about others. Further, caregivers help toddlers learn to label feelings and emotions and to manage and cope with strong emotions.

Critical Thinking Skills

Toddlers are eager learners and capable problem solvers. Caregivers need to provide environments rich with opportunities and materials to expand toddlers' natural intuitions to learn through exploration and experimentation. Success builds on success as toddlers tackle ever more difficult problems and develop persistence. Caregivers encourage critical thinking skills by providing opportunities for mathematical understanding (e.g., number sense, patterns, categorization, sorting), scientific curiosity (e.g., experience with the nature world), and creativity (e.g., building with blocks, through creative expression in art, movement, and music).

Development of Communication and Literacy Skills

Central to development the first 3 years and to the emergence of literacy are verbal and nonverbal

communication by using and understanding words, signs, and symbols. This development is facilitated by attentive toddler caregivers as they provide opportunities for meaningful conversation between individuals (adult-toddler and toddler-peers), plenty of books and numerous times for lap-time one-on-one and small group reading, varied and diverse writing and drawing tools and materials, and time and materials for dramatic play.

Physical Skills Development

As toddlers move through and about the toddler room, they are both developing and using small and large muscles that, integrated with their senses, create essential brain connections. Sensory integration works to help toddlers become increasingly more coordinated and to develop important balance and physical stabilities necessary to act as sensorimotor learners as they explore and play in their environments. (Sensorimotor learners explore using all five of their senses and their large and small muscle skills.)

Development of Self-Help and Personal Care Skills

Along with a growing sense of self in toddlers often comes a strong and emphatic desire to do things on their own—"Me do it!" Throughout toddlerhood, the child grows in capacity to help others (to be prosocial, as discussed earlier) as well as to engage in more of his or her own personal care needs. Toddler caregivers can encourage age- and culturally appropriate independence in areas of eating, toileting, dressing, and completing hygiene tasks.

By creating, implementing, and continuously assessing high-quality environments, supportive relationships, and thoughtfully planned experiences, professional caregivers optimize healthy overall growth, development, and learning for each and every toddler in the toddler room.

TOOLS OF THE MIND

Tools of the Mind is a comprehensive early childhood curriculum for preschool and kindergarten-age children and a professional development program designed to train teachers and administrators in Tools-specific pedagogy. Since its inception in the mid-1990s, Tools of the Mind has been implemented in a variety of early childhood settings including public and private preschools and kindergartens, charter schools, Even Start, and Head Start programs. Demographic composition of children in Tools classrooms is fairly diverse and includes high-poverty schools, ethnic minorities, children with special needs, and dual language learners. The educational backgrounds and experience of Tools-trained teachers also vary; those who have received the training include experienced teachers with master's degrees, Head Start assistants with GED certificates or high school diplomas, and graduates of alternative teacher education programs such as Teach for America. This entry explores the philosophical foundations of Tools of the Mind, including its debt to the educational theories of Lev Vygotsky. Further consideration is given to the curricular and pedagogical foundations of Tools of the Mind and to teacher preparation for the Tools classroom.

Philosophical Foundations of Tools of the Mind

Tools of the Mind is grounded in the cultural-historical theory of child learning and development

associated in the West with Vygotsky and Alexander Luria. It also draws from the basic and applied research conducted by several generations of post-Vygotskians, including Alexander Zaporozhets, Daniel Elkonin, Piotr Galperin, Vasily Davydov, and Leonid Venger.

Since Vygotskians identify intentionality and self-regulation as major outgrowths of the early childhood years that are necessary prerequisites for school success, promoting self-regulation is one of the main focus areas in Tools of the Mind activities. The design of these activities is based on the Vygotsky-Luria ideas of the development of intentionality and is also informed by the latest findings in the field of developmental neuropsychology and especially the research on the development of executive functions.

The core idea of Vygotsky's cultural-historical theory is that the history of human development is a complex interplay between the processes of natural development that are determined biologically and the processes of cultural development brought about by the interaction of the growing individual with other people. It is through these interactions that children learn to make use of such culturally developed tools as language or nonverbal external *stimuli-media* to organize their own behavior. The acquisition of these cultural tools—tools of the mind—does more than just allow a child to perform better on a specific task; it actually promotes the restructuring of the child's brain through the development of higher mental functions, including *deliberate*, *mediated*, and *internalized* behaviors.

This view of child development calls for a different approach to education, an approach that focuses instruction not on the competencies the child already has, but on the competencies that are still under construction—the ones that exist in the child's zone of proximal development (ZPD). Vygotsky believed that the role of the teacher involves more than teaching facts and skills—teachers can actually shape children's development by helping them acquire tools of the mind.

Specific implications of this principle for early childhood education can be summarized in the idea of amplification. The term *amplification* was coined by Vygotsky's colleague Zaporozhets as the

answer to the “push-down” curricula that turn the preschool classroom into a miniature copy of a primary classroom with teaching methods and materials modeled after the ones used by elementary teachers. The idea of amplification was also intended to offer an alternative to the notion of “spontaneous development” of young children—the idea that development could not and should not be affected by instruction. Amplification focuses on the role of education in child development, emphasizing that properly designed educational interactions do not stifle the development of young children but instead promote it, thus presenting a logical extension of Vygotsky's principle of instruction promoting development.

Vygotskians identify certain “leading activities” that children engage in and that produce the greatest gains in development. These leading activities are age specific and provide the best conditions for the acquisition of cognitive and social competencies most critical for child development at this age. In addition, when engaged in a leading activity appropriate for their age, children develop prerequisites for the competencies that enable them to successfully transition to the leading activity specific to the next age level. According to this theory, make-believe play is the leading activity of preschool and kindergarten-age children, while for students in primary grades, it is intentional learning (frequently referred to as the “learning activity”). Among the important benefits of play for young children is the development of their ability to regulate their behaviors as they learn to follow the rules associated with the roles they play. Vygotskians do not believe that play develops spontaneously in all children once they reach preschool age; well-developed or mature play, the level necessary for play to become a leading activity, emerges only with adult mediation or when young children are assisted by older children acting as play mentors.

Tools of the Mind Content

As a comprehensive curriculum, Tools of the Mind covers all subject areas and all developmental domains specified in federal, state, and local standards documents. However, in doing so, Tools of

the Mind follows developmental trajectories for the underlying competencies ensuring mastery of these subjects by 4- and 5-year-olds, rather than replicating the scope and sequence found in the curriculum materials initially designed for older children.

An example of such a Tools-specific approach is teaching early literacy in the context of children's own writing. Vygotskians see the value of learning to write not in merely preparing children for formal schooling, but in acquiring an important cultural tool critical in supporting the development of higher mental functions. Consistent with this view, writing is introduced in Tools classrooms in the context of children's planning their play, so that the writing is meaningful and relevant to children's lives. In using their plans for play—first pictorial and later written—to remind themselves and their peers of each other's play roles, children pay attention to their marks on paper and their relation to oral messages, which in turn facilitates their “breaking the code” of written language. Teaching children to plan their messages prior to writing them down by using the Scaffolded Writing technique, unique to Tools, makes it even easier for children to learn to read and write.

To help children develop intentional self-regulated behaviors, self-regulation practice is embedded in all activities across subject areas. This practice takes different forms as children engage in other-regulation working with their partners, use private speech (self-talk) to regulate their own behavior, or make use of external (tangible or pictorial) mediators to self-direct their attention to specific aspects of a task. An example of such embedded self-regulation activity is Buddy Reading, whose primary focus is teaching children about print. Children are to take turns “reading” to one another. To support self-regulatory behaviors, the teacher uses visual representations, giving one child in each pair a drawing of lips and the other child a drawing of an ear, explaining that “ears don't talk; ears listen.” Children then trade drawings and roles, thus learning how to enact the social norms of taking turns and waiting one's turn.

In addition, specific focal activities are designed to provide children with practice in certain aspects of self-regulation. For example, playing a version

of the freeze game, children practice regulating their physical behaviors as they move when the music plays and “freeze” when it stops in the position portrayed on a card held up by the teacher. In kindergarten, children practice planning and monitoring skills as they create learning plans, set their learning goals, and discuss their performance relative to these goals during weekly learning conferences with their teacher.

All activities in Tools of the Mind are designed for a 3-year age span, so that children in the classroom can participate in the same activity regardless of their developmental and/or chronological age. The content level for each child is adjusted up or down to provide challenge at each child's initial level. For example, in a counting game, all of the children count objects, but one child counts numbers under five while another child is given numbers over 20. In addition, the activity is made more challenging over time in response to children's learning, so that as the activity unfolds, an advanced “counter” may be counting by fives or exploring place value, while another child is working on numbers between 10 and 20.

Attention to play is one of the hallmarks of a Tools of the Mind curriculum. In Tools preschool classrooms, children spend a significant amount of their day (around 60 minutes) playing, and play is modeled, scaffolded, and organized in a particular way to ensure that children create an imaginary situation, act out well-defined roles, and follow the rules built in the pretend scenario. In Tools kindergartens, children continue to acquire and refine their play skills as they engage in play dramatization, creating and acting out pretend scenarios based on literature they study in class. Strategic choice of the literature ensures that children use their play to master science and social studies content along with rich vocabulary.

Tools of the Mind Pedagogy

The pedagogy used by Tools of the Mind teachers is based on the concept of individualized scaffolding within each child's ZPD, as determined by the teacher through Dynamic Assessment. Dynamic Assessment is used to establish both the child's

current level of achievement and the child's potential ability to attain higher levels. When used in a classroom, Dynamic Assessment consists of a series of prompts and hints provided by the teacher. Skills and understandings that children demonstrate as a result of minimal assistance are considered closer to being developed and are then chosen as a focus of immediate instruction.

Teachers in the Tools classrooms use the results of Dynamic Assessment to determine which scaffolding strategy works best with each individual child or with a group of children with like needs. These scaffolds are described in the teacher's manual and taught to the teachers during the training sessions. In addition to the range of scaffolding strategies aimed at typically developing children, special strategies are included to support children with special needs and dual language learners. Tools teachers also learn to use Dynamic Assessment to determine whether the level of support can be removed, as the child is more and more capable of doing the activity on his or her own. Scaffolding strategies go beyond one-on-one interactions and include the use of external mediators, private speech, and specially designed interactions with peers. Children's increasing levels of self-regulation allow Tools teachers to minimize whole group instruction and spend more time providing scaffolding to individual children, especially the ones who need extra support or extra challenges.

Tools of the Mind Professional Development

The Tools professional development program also follows the Vygotskian approach, scaffolding teacher learning through a system of coaching, workshops, and self-reflection activities designed to provide teachers with an understanding of learning processes and specific instructional tactics undergirding each activity. Teachers attend four workshops spread over the course of a school year to learn Tools activities and the basic principles of learning and development underlying activities. The next year, teachers attend three more workshops, in which they learn more about the philosophy behind Tools and also deepen their

understanding of how to scaffold children's learning individualizing each activity. Depending on the size of the program or the school district participating in the professional development, special workshops are offered for the other educators such as administrators, special education teachers, bilingual and English as a second language teachers, and parent liaisons. Whenever possible, Tools encourages paraprofessionals to attend the same workshops teachers attend as they work with teachers, forming a teaching team.

Tools of the Mind uses two models of professional development that differ in how teachers are being supported throughout a school year. The first one is high touch and involves extensive technical assistance delivered by Tools trainers to the program's teachers and coaches. This model is mostly used with large urban districts and other programs that have the necessary resources and a higher concentration of classrooms in the area. Recently, in its attempt to serve smaller and more geographically dispersed programs by offering a new model of professional development that makes greater use of technology, Tools of the Mind has developed the iScaffold, a tablet application that works as an on-demand coach with videos, developmental trajectories, and quick-start guides that assist teachers between workshops to master activities and their underlying principles.

Evidence of Tools of the Mind Effectiveness

Tools of the Mind has been the subject of multiple studies ranging from large-scale randomized trials to the evaluations conducted by individual programs and school districts. It is one of a very few early education programs that has documented effectiveness of classroom-based intervention in influencing children's levels of self-regulation both in preschool and in kindergarten. In addition, the research on its implementation in kindergarten classrooms has shown that Tools can help close the achievement gap, and that the children continue to show benefits after they exit the program. Independent evaluations of Tools show two key outcomes of implementing Tools: (1) It helps to

overcome school readiness deficits associated with being educationally at risk and (2) it affects children's academic learning in and beyond kindergarten. The benefits of the intervention continue after the students exit the program. The new research even shows an effect on stress physiology by measuring stress hormones of children in the classroom, something no other program to date has been able to show. Researchers attribute these outcomes to Tools' emphasis on short-term memory and the ability to concentrate on new information, regulate attention, control impulses, and regulate behaviors and emotions. These results produced in independent evaluations are replicated by the results found by school districts, Head Start programs, and early childhood programs using the program in populations that range from urban to rural and from at risk to middle class.

These results are particularly important in the context of the public discourse about the goals of early childhood education and the means to achieve these goals. This discourse has been dominated by two competing views on what early childhood education should be about. One view advocates an early focus on discrete skills tightly aligned with achievement standards. Proponents of this view downplay research findings indicating that this approach can affect academic achievement only in the short term. However, the benefits found in many of these intervention studies fade and do not seem to carry over to the following grade levels. On the other hand, the proponents of the whole-child approach (including many early childhood educators and parents) are having difficulty in meeting ever growing demands for accountability. Supporters of the approach embodied in Tools of the Mind argue that this dichotomy is a false one and that focusing on underlying cognitive and noncognitive competencies in the context of play and playful learning not only ensures that children meet immediate academic and social demands of formal schooling but also allows them to develop a strong foundation for success in a variety of contexts both in school and beyond.

TRANSDISCIPLINARY COLLABORATION

Transdisciplinary collaboration is a partnership that emphasizes sharing of information, decision making, and implementation of plans among professionals in early intervention. The purpose of this collaboration is to maximize efficiency and effectiveness of early intervention services. Transdisciplinary collaboration requires a significant commitment to planning and problem solving by team members. Team members may include individuals from a variety of professions including but not limited to early childhood specialists, speech-language pathologists, nurses, social workers, physical therapists, and occupational therapists. Family members and caregivers are always central to any transdisciplinary team. The components of transdisciplinary collaboration separate it from other types of collaborative models such as multidisciplinary and interdisciplinary models of collaboration. Since its development in the 1970s, transdisciplinary collaboration has been described through aspects of implementation as well as strengths and challenges to its use within the field of early childhood.

Components

Two commonly mentioned components of transdisciplinary collaboration are *arena assessment* and *role release*. The goal of arena assessment is to conduct an integrated, comprehensive developmental evaluation. During arena assessment, one or a small group of team members referred to as *facilitators* engage with the child during assessment while other team members observe the interaction. The facilitators are responsible for eliciting behaviors from the child across developmental domains such as speech, physical movement, cognitive skills, and so forth. Facilitators often include a caregiver and a professional from the team. Arena assessment enables multiple disciplines to complete assessments during a single assessment visit. Arena assessment is intended to decrease the demand on the family and child when multiple assessments are required. Arena assessment requires team members

to be knowledgeable about the goals and methods of assessment across disciplines.

Role release is another core component in transdisciplinary collaboration. Role release occurs when one team member releases implementation of his or her discipline-specific goals to another team member. Role release is present in arena assessment as the observing team members release elicitation of their individual assessment items to the facilitators. Role release may also occur during intervention when one or a small number of team members provide direct service with a family while remaining team members take on a consulting role. The team members responsible for direct service provision are often referred to as primary service providers (PSPs). For example, the early childhood specialist may be the PSP, going into the home once per week and providing intervention focused on language development and acquisition of cognitive milestones. The speech-language pathologist may meet with the early childhood specialist to provide consultation but not actually attend the weekly visits with the family. Role release is designed to promote collaboration across disciplines and to facilitate a strong relationship among a small number of providers and the family.

There must be fluidity to the practice of role release that enables changes in the PSP or increases in numbers of PSPs as the needs of the family change. For example, a family working with the early childhood specialist on language development and cognitive milestones may begin to need assistance in feeding as the child is transitioning to solid food intake. The occupational therapist or speech-language pathologist may need to be added as a PSP to address self-feeding and oral motor prerequisites to solid food intake. This addition of PSPs as needed is a result of ongoing collaboration among team members.

Role release is often the component of transdisciplinary collaboration most discussed. However, role release is the culmination of other components of transdisciplinary collaboration including role extension, role enrichment, role expansion, role exchange, and role support. The components are focused on increasing knowledge of one's own discipline, sharing that knowledge

with other team members, and learning to integrate knowledge, beliefs, and practices across disciplines. Underlying these components is the philosophical principle that a child's development is integrated across developmental areas. For example, a child's motivation to begin crawling may be prompted when his cognitive understanding tells him that the favorite toy now exists even when it is under the blanket. The critical cognitive skill of object permanence is tied to the physical milestone of crawling.

Components of transdisciplinary collaboration are supported by consistent and intensive team consultation. It is critical that members of the team are philosophically agreeable to a significant level of integration. It is also important that team members have personalities that work well in teams including willingness to problem solve collectively and find mutually agreeable solutions to problems. Family members are core members of the team and take on active roles in problem solving, planning, and implementation.

History

Transdisciplinary collaboration was initially described in the 1970s as part of the National Collaborative Infant Project by United Cerebral Palsy. Transdisciplinary collaboration represented more intense collaboration than other types of early intervention teams including multidisciplinary and interdisciplinary teams. The transdisciplinary collaboration represented one end of a continuum of collaboration rather than a completely separate type of early intervention team. A team utilizing transdisciplinary collaboration may very well be a team that has been together for years in order to establish the trust and expertise necessary to fully implement this model. However, implementation of transdisciplinary collaboration can be done over time with concerted efforts.

Implementation

Intensive collaboration fundamental to successful transdisciplinary collaboration has its foundation

in team building. The first component of team building is structural support. There needs to be prioritization of establishing an effective team, and that requires time. Time spent in team building necessitates financial resource allocation. Teams need to establish collective goals that often begin with elements of role extension, enrichment, and expansion. Team members individually set goals to learn more about their own discipline and to be open to learning from other team members about their disciplines.

The next step in implementation of a transdisciplinary collaboration is to begin to have shared discussions about discipline-specific information such as assessment procedures, developmental milestones, and therapy strategies. Shared vocabulary develops among team members as team members discuss aspects of intervention, theories, and practices. Implementation of core components such as role release and arena assessment is the outgrowth of team building.

It is recommended that significant time be spent with team members prior to implementation and that implementation is practiced with confederate families prior to use with actual families. This practice with confederate families enables team members to identify challenges including lack of knowledge, difficulties with blurred boundaries, and logistical challenges to implementation.

Implementation of transdisciplinary collaboration with the family should begin with the intake from families at the onset of services. Intake should be a time to encourage families to share information, enabling the family to guide the intake discussion. Providing families with the opportunity to share more than simply short answers to a few key questions about concerns, family history, and medical history helps to establish families as active team members and collaborative partners.

As teams implement role release during intervention, continued team meetings are necessary. During team meetings, members plan and problem solve. At times, additional primary service providers may be added for short periods based on needs of the family.

Strengths of a Transdisciplinary Model

Positive outcomes of transdisciplinary models described in the literature include the following:

- Decreased wait times for children to enroll in services
- Increased attendance for families involved in early intervention groups
- Decreased costs associated with assessment and intervention
- Ease of scheduling for families due to decreased number of weekly visits
- More holistic view of the child due to increased integration of developmental domains
- Consistency in message communicated to family because of interdependence of team members

These strengths are indicative of the focus of transdisciplinary models on efficient and highly collaborative service delivery. Systematic research on transdisciplinary collaboration in early intervention is lacking as most investigations are descriptions of implementation with preliminary quantitative and qualitative feedback. Large-scale investigations comparing types of collaborative models in terms of early intervention outcomes are encouraged to validate the preliminary strengths discussed currently in the literature.

Challenges of Transdisciplinary Collaboration

Descriptions of models have also highlighted challenges to implementation including the following:

- Need for intensive, ongoing team meetings
- Need for philosophical alignment of team members
- Need to view all team members as equivalent members
- Integration of knowledge of different disciplines
- Use of therapy strategies that may originate from another discipline

An ongoing challenge to transdisciplinary collaboration relates to assembly and maintenance of transdisciplinary teams. Embedded in this discussion are

philosophical alignment of members, trust among team members, and time to devote to team meetings. Suggestions for meeting these challenges range from establishing a minimum number of years working together prior to beginning this type of collaboration, to philosophical assessments of team member prior to beginning, to team-building activities, to formal mentorship programs for new team members. Reflective practice as a team is a critical component to ensure that as personnel changes, the team continues to function as a transdisciplinary team. Teams must always be asking if they are still adhering to the tenets of transdisciplinary collaboration.

Conclusion

Transdisciplinary collaboration represents an early intervention team model that maximizes interprofessional collaboration and emphasizes active family participation. The model has been discussed in terms of components, implementation, and strengths and challenges since the 1970s. Its dependence upon shared knowledge and shared roles during assessment and intervention differentiate it from other types of early intervention team models. While it offers cost benefits to implementation of early intervention services to the family, it requires significant financial commitment to establish proficient transdisciplinary teams. Transdisciplinary collaboration continues to need additional empirical investigation into implementation and effectiveness.

TRANSFORMING THE WORKFORCE

Children's development is rapid and cumulative from birth through age 8, when the environments, supports, and relationships they experience have profound effects. Their health, development, and early learning provide a foundation on which later learning—and lifelong progress—is constructed. Children experience important influences from many adults during this time period, including their parents or other primary caregivers, other family members, community members, and the professionals who provide for their care and education, health, and security. An Institute of Medicine and National Research Council study explored the science of child development for its implications for the care and education professionals who work with children from birth through age 8. This entry summarizes the major findings of the resulting report, *Transforming the Workforce for Children Birth Through Age 8: A Unifying Foundation*.

The study that resulted in the report was carried out by the Committee on the Science of Children Birth to Age 8: Deepening and Broadening the Foundation for Success, a group of expert volunteers convened from October 2013 through March 2015. The study found that much is known about how children develop and learn, what care and education professionals need to know and be able to do, and what professional learning supports they need. This knowledge has increasingly informed standards and frameworks articulating what *should be*, but it is not fully reflected in what *is*—the current capacities and practices of the workforce, the nature of the environments in which they work and the conditions of their employment, the policies and infrastructure that set qualifications and provide professional learning, and the support and oversight provided by government and other funders.

The science of child development and early learning makes clear the importance and complexity of working with young children from infancy through the early elementary years. It also illuminates the need for consistency and continuity in early care and education both over time as children develop and across systems and services. Yet just when children would benefit most from high-quality learning experiences on a consistent, cumulative trajectory, the systems they encounter are fragmented. The care and education of young children take place in many different programs and settings. They have different practitioner traditions and cultures; they are funded through multiple governmental and nongovernmental sources; and they operate under the management or regulatory oversight of diverse agencies with varying policies, incentives, and constraints. Despite their shared objective of nurturing and securing the future success of young children, those who work with these young children are not acknowledged as a cohesive professional workforce, unified by the common knowledge base and competencies needed to do their jobs well.

The gap between what the science tells us about child development and early learning and the systems and policies currently in place exists in part because these policies and systems do not place enough value on the knowledge and competencies

required of professionals in the workforce for children from birth through age 8, and the expectations and conditions of their employment do not adequately reflect their significant contribution to children's long-term success. The breakdowns that have led to this gap include the lingering influence of the historical expectations and status of various professional roles that entail working with young children; limited mutual understanding, communication, and strategic coordination across decentralized and diverse communities of practice and policy; and limited resources for concerted efforts to review and improve professional learning systems. These disconnects and limitations serve as barriers to both improving how the current workforce is supported and transforming how the workforce needed for the future is prepared.

The report offers a blueprint for action to achieve better support for these care and education professionals. It is based on a unifying foundation that encompasses essential features of child development and early learning, shared knowledge and competencies for care and education professionals, and principles for effective professional learning.

Within this blueprint, the report offers recommendations, for example, to achieve greater quality and coherence in professional learning supports, both in higher education and during ongoing practice. Those who provide care and education for infants and toddlers and those who practice in settings outside of centers and schools, such as family child care, need greater access to infrastructure for professional learning. For early elementary educators, the competencies needed to work with the youngest students can be overshadowed in broader K–12 professional learning systems that skew toward the education of older children.

Practices and policies regarding requirements for qualification to practice vary widely depending on the professional's role, ages of children with whom he or she works, practice setting, and which agency or institution has authority for setting qualification criteria. The report recommends that agencies and organizations that oversee care and education strengthen and align competency-based qualification requirements for all care and education professionals working with children from birth through age 8. Specifically for all

lead educators, meaning those who bear primary responsibility for instructional and other activities for children in formal care and education environments, the report calls for phased, multiyear pathways to transition to a minimum bachelor's degree requirement with specialized knowledge and competencies.

The science clearly indicates that the work of lead educators for young children of all ages requires the same high level of sophisticated knowledge and competencies related to child development, content knowledge, and educational practices. Holding lower educational expectations for educators working in preschools, centers, and other settings with children in their youngest years than for those working in early elementary grades perpetuates the perception that educating children before kindergarten requires less expertise than educating older children, which helps to justify policies—such as for compensation, program funding, and professional supports—that make it difficult to maximize the potential of young children and the early learning programs that serve them. Given the complex issues that accompany a minimum degree requirement, this change will require careful implementation over time and in the context of efforts to address multiple interrelated factors that affect the quality of professional practice.

The report's recommendations also address evaluation and assessment of professional practice, the role of leadership, interprofessional practice, improvement of the knowledge base, and support for implementation at the local, state, and national levels. The report also offers a detailed framework for collaborative change as well as extensive discussion of considerations for implementation, recognizing the challenges of making multiple and interdependent changes that will require strategic prioritization of immediate actions as well as clearly articulated intermediate steps to achieve long-term goals. Significant mobilization of resources will be required, with investments from government at all levels and from nongovernmental sources. Therefore, assessments of resource needs, mobilization of funding, and financing innovations will be important.

Many of the challenges discussed in the report are not new. If the needs of the professionals who

work with young children continue to be neglected, it will perpetuate a fragmented approach to early care and education that results in inadequate learning and development of young children, especially among the most vulnerable families and communities in the United States. The changes recommended in the report hold promise for improving the quality of professional practice, the quality of the practice environment, the status and well-being of the workforce, the recruitment and retention of a robust pipeline of new professionals—and ultimately, outcomes for children. It is through the quality work of these adults that the nation can make it right from the very beginning for its children.

TRANSITION TO PARENTHOOD

The birth of a child constitutes a major, if normative, transition in the life span marked by dramatic changes in psychology, sociology, and health. Many dramatic role changes accompany the advent of parenthood, including redefinition of identity, psychological preparation, realignment of relationships, and eventually negotiation of child

care responsibilities, and the transition to parenthood is moderated by multiple factors. It is little wonder that a book titled *What to Expect When You're Expecting* has long tenanted the best-seller list. All that said, the transition to parenthood is only one stage in the individual and family life course. This entry covers stages of the transition to parenthood and variability in them, the demographics and biology of the transition, family systems and the transition, moderators of the transition, methods of studying the transition, and determinants of the transition.

Stages of Parenthood and Variability

The transition to parenthood may turn on a defining moment when a child is born, but its boundaries—when the transition to parenthood actually begins (in childhood playing house, in courtship, at marriage) and when it ends (if it ever does until the parent dies as children constantly change and so the requirements of parenthood do)—are less well defined. Becoming a parent itself consists of several stages in which parents refocus their thoughts, feelings, and behaviors. For example, parenting cognitions cast a long shadow: Mothers' antenatal attachment expectancies and representations toward their unborn child predict mothers' expressed sensitivity postnatally. Because no criteria for successful parenthood are known, the transition to parenthood is also fraught with uncertainty.

It needs to be understood, too, that there is no uniform transition to parenthood because pregnancy may occur before or after marriage, education, and career; because people may transition to different types of parenthood as married, step, foster, or adoptive parents; and because multiple processes of change that normally accompany the transition to parenthood in self-efficacy expectations, gender roles, personal control, information seeking, anxiety, and depression likely follow different paths. Adaptation to the arrival of a baby may have joyful or negative consequences for the quality of marital relationships (which tends to suffer a slight deterioration) and for the division of household labor between spouses (which tends to

become more traditional). A given parent might also be in multiple stages of parenthood with children of different ages.

Although there is great variability, identifiable changes occur from pregnancy to a few months postpartum: Normatively in this period, parenting self-efficacy, life satisfaction, and conflict increase (over the long and short term), and depression and anxiety (about labor or health of the fetus) and marital relationship satisfaction decrease (these negative marital relationships may be significant at the time but are not necessarily of lasting importance). Women's interest in domesticity also increases after they become mothers. Furthermore, marital relationships and level of involvement during the process of becoming a parent do not transit independent patterns of change, but development of both dimensions mutually influence one another.

Demographics and Biology of the Transition to Parenthood

In the United States, the vast majority of people (80+%) become parents, the average age at first birth is approximately 25 years, and the average relationship length when couples have their first child is approximately 3 years (Bornstein, 2015). However, teenage motherhood is epidemic (273,105 live births in the United States in 2013 [Centers for Disease Control and Prevention/National Center for Health Statistics, 2015], as approximately one in three adolescent women becomes pregnant by the end of her 19th year [Bornstein, 2016]), and increasing numbers of adult women are delaying conception, extending the age range for pregnancy, birth, and the transition. These demographic trends are ascribable to several factors that contribute to the decision to bear a child and so the transition to parenthood, and they apply to first-time parenthood. For example, the widespread availability of contraception (and to some degree assisted reproductive technologies) has rendered decisions of whether and when to bear children elective. Yet, the rates of unintended and intentional pregnancies are about the same. Notably, transitioning to unplanned parenthood is associated with many poorer forms of

parenting, increased likelihood of perinatal mood problems, and reduced well-being. Changing cultural mores also permit increasing numbers of people to reject parenthood or to terminate pregnancies and so remain voluntarily childless.

Family Systems and the Transition to Parenthood

Individuals function, not in isolation from one another, but as part of a family. Families are systems composed of subsystems of interconnected and interdependent individuals. The transition to parenthood involves family systems. Systems undergoing change are especially volatile, and as the family moves from one stage of its life cycle (childless) to the next (parenthood), equilibrium established during the former stage is disrupted by changes in one or more family members and the complexification of the network of family relationships. In the transition to parenthood, the family system expands from a single dyadic couple relationship to include a mother-child relationship, a father-child relationship, a triadic relational system, and an emerging coparenting component to the couple relationship. This important developmental transition can only be fully understood within a systems perspective, as all the individual- and interpersonal-level processes of change that men and women undergo when becoming parents are normally interrelated and mutually influence one another.

Moderators of the Transition to Parenthood

As suggested, the transition to parenthood is inherently heterogeneous as it is moderated by several factors, including how the family system is built, the stage of life of the parent, how old the parent is, and other sociodemographic factors, such as parity, ethnicity, and work status.

Biology Versus Adoption

Most parents are biologically related to their children, but the adoption and rearing of children by adults who are not biologically related has a

long history (regulations concerning adoption can be found in the Code of Hammurabi, 1750 BCE), and adoption is common in all cultures. The transitions to parenthood by parturition and by adoption differ. That is, giving birth to versus adopting a child differentially affect the development of parental identity and influence subsequent parenting behavior, and biological and adoptive parenthood each entails unique tensions and stresses. Parents are normatively members of cultures that expect they will give birth to their child. Adoptive couples may therefore approach parenting and the transition to family life with atypical cognitions that in turn influence their transition into parenthood. For example, when parenting is unplanned versus planned (as adoption must be), marital feelings and relationships may follow different courses, and relative to biological parents, adoptive parents face different challenges (e.g., acceptance of infertility) that impact their progression through the transition to parenthood.

Biological and adoptive parenting each has positive and negative consequences. By some reports, parents who adopt or gain a stepchild report greater life satisfaction than parents who birth a biological child, and those parents do not necessarily experience adverse well-being during the transition to adoptive parenthood, despite the stressors associated with adoption. The transition to parenthood for stepparents may be associated with relatively less stress because stepchildren are almost always older and presumably less challenging to care for than are newborn biological children (although stepparenthood is associated with its own challenges). Moreover, parents who acquire a stepchild are also usually newly married, and getting married is linked with enhanced well-being.

Mother Versus Father

The transition to parenthood is not the same for mothers and fathers, and so engenders the need to conceptualize two different transitions: the transition to motherhood and the transition to fatherhood. The transition to parenthood is accompanied by readjustments and changes that reflect important gender differences and that operate on structural as

well as biological levels. Of course, more is known about the transition to parenthood in women. Although women and men undergo substantial biological changes in the transition to parenthood, after all only women actually give birth. Social factors, such as maternity leave, may further accentuate differences in mothers' versus fathers' involvement during and after the transition to parenthood. In short, it is inappropriate to generalize about the transition to parenthood across gender.

Age

As suggested, people transition to parenthood at widely varying ages, and so the timing of parenthood affects the transition. Younger and older parents are differently prepared. Generally, adolescent mothers and fathers appear less able or likely than adult mothers and fathers to negotiate the transition smoothly because of experiential factors or on account of teens' own levels of ego development, emotional maturity, attitudes and expectations, and cognitive limitations. Teenage parents may possess less complex and multilevel beliefs about parenting and certainly command fewer resources than adult parents. In essence, developmental demands of adolescence and parenthood compete. Life events that often co-occur with becoming a young mother include having a low birth weight or preterm infant, having a sick infant, becoming depressed during the pregnancy or after the birth, changing residence or school attendance patterns, and suffering a constricting social network.

Other Moderators

Numerous other factors likely moderate the transition to parenthood. For example, the family system undergoes different changes with the birth of a first versus a later child. As they transition from primipara to multipara, parents report having less free time, enjoy fewer financial resources, feel more overwhelmed and tied down, endure increased strain at work due to the need to make more money, and experience more stress at home because of the need to care for additional children.

Features of the transition to parenthood, such as marital conflict and tensions, vary in parents of different ethnicities. Participation in the labor force or not alters the transition to parenthood, and the work statuses of parents generate ecologically different family systems. In families where both parents-to-be are wage earners, both parents may need to be more involved in the care of children. Last, first-time adult civilian versus military parents face different challenges, have access to different supports, and follow different paths in the transition to parenthood.

Methods of Studying the Transition to Parenthood

Beyond personal phenomenology, what is known about the transition to parenthood derives from scientific research designs of different sorts, but usually focuses on questions of stability/instability and continuity/discontinuity experienced by each individual and each couple during the process of becoming parents. To explore changes and adaptations that take place across the transition to parenthood, parents are most often studied longitudinally, that is, before and after the birth of a child. Longitudinal within-subject designs provide for powerful analyses, as this approach controls for variance due to additional individual factors, such as gender, personality, and so forth. However, this strategy can be flawed. Consider the assessment of well-being. If well-being is first assessed during pregnancy, researchers need to interpret any subsequent change in well-being across the transition to parenthood as a change from its pregnancy level, not as a change from some "true" baseline in the person, because pregnancy itself is likely associated with improved well-being. Ideally, then, longitudinal baselines should be established over multiple assessments prior to pregnancy (or adoption). Longitudinal studies that examine some dependent variable of interest across the transition to parenthood commonly only assess that dependent variable over a relatively short period of time. However, children typically reside with their parents for close to 2 decades and maintain relationships with their parents throughout

their lives, so examining some dependent variable in parents even, say, over the first 5 years after the transition to parenthood yields only a narrow perspective. Alternative between-subject designs compare parents with nonparents across the parent's transition to parenthood, but these designs too of course have advantages and disadvantages.

Determinants of the Transition to Parenthood

People appear to be differentially prepared for parenthood and experience the transition to parenthood differently. Why? Greater personal growth in the transition to parenthood has been reported by mothers than fathers and by parents of premature infants than those of full-term infants. Demographic characteristics also contribute, with greater growth predicted in younger age and lower education parents. Understanding individual variation in the transition to parenthood calls for information about the biological and psychological characteristics of each individual in the family; these include differences attributable to persons rather than to situations, such as gender (mother vs. father and male vs. female child), ethnicity, socioeconomic status, and family type (e.g., married, divorced, step, foster, adoptive) as well as sociocultural context, relationships in parents' families of origin, and the relationship between the parents, with special emphasis on their division of roles, communication patterns, and coparenting. Autonomy during pregnancy predicts well-being across the transition to parenthood, and sense of control is associated with fewer symptoms of anxiety and depression across this transition. Relationships between nuclear family members and key individuals or institutions outside the family (friends, peers, workmates, child care, school, ethnic group, government) also matter as sources of stress, support, models, values, beliefs, and behaviors.

Thus, characteristics of the parents (e.g., timing of the transition to parenthood, such as early or late), characteristics of the child (e.g., term or not, easy or difficult), and characteristics of the family (e.g., structural differences, such as single, adoptive,

or step) all matter to the transition to parenthood, as do cohort effects (effects of sociohistorical experience on development as manifest by different generations because what is known about the transition to parenthood at any one time may be unique to the cohorts studied and not generalize to other generations of parents). For example, current research that examines the impact of social change (such as female participation in the workforce, gender roles, increasing use of child care, adult children at home, and/or alternate family structures) on the transition to parenthood may be applicable only to the here and now.

Stress and Personality

New parents experience changes in their personalities. Personal stress and marital stress increase during this transition. Although new parents experience an increase in well-being soon after the birth of their child, this increase normatively dissipates within the first year. Generally during the transition to parenthood, gender roles become more traditional, with women becoming the primary caregiver, and marital satisfaction also often declines.

Cognitions and Information Seeking

Expectations of the division of labor in parenting are normally optimistic and may deviate from actual involvement that takes place after the birth. The extent of the mismatch between expectations held during pregnancy and the real level of partner involvement constitutes violated expectations that often heighten dissatisfaction and lead to decreases in contentment and relationship satisfaction.

Women actively seek information in anticipation of a first birth, use this information to construct identities incorporating motherhood, and change the information they need as the event comes closer (i.e., information seeking about labor is greatest in the second and third trimesters, information about child care in the third trimester). Such information is a primary determinant of self-definitions of motherhood in middle-class European American women living with a male partner.

Internal Working Model

A mother's perceptions of parenthood are influenced by her attachment relationships and representations, by her own experiences from childhood and adolescence, and by the infant. Aspects of the mother's past are thought to activate during the transition to her own parenthood. For example, attachment insecurity is associated with greater parenting stress and more psychological distress during pregnancy and the transition to parenthood. Research into intergenerational parenting concerns itself with the transmission of beliefs and behaviors across generations. For better or worse, parenting patterns are often passed down within families.

Child Effects

Parents of infants with relatively easy temperaments (low in fussiness/difficulty) report experiencing more positive changes across the transition to parenthood than parents of infants with difficult temperaments. So, individual differences of all sorts in children make a difference in the transition to parenthood.

Social Support and Coparenting

Social support refers to the psychological and tangible resources available to individuals through their relationships with family, friends, neighbors, workmates, and others. Both informal support systems (the extended family) and formal ones (schools, child care, parent education programs, and professionals) influence the transition to parenthood. Support from husbands is associated with good adjustment in all areas during pregnancy and postpartum. Women experiencing a difficult adjustment turn to support networks. Integration or isolation from potential support networks mitigates or exacerbates the course of the transition to parenthood. On average, coparenting experiences are positive and stable over the first 6 months of parenthood, but fathers typically are more satisfied with coparenting than are mothers. The prebirth marital relationship and especially fathers' positive marital interactions are important indicators of whether

both parents feel supported and validated in early coparenting. Violated expectations for the division of child care predict the ways in which coparenting experiences unfold. Support from family members and other groups is associated with more successful transitions to parenthood. For example, supportive relationships predict less parental depression and greater psychological adjustment after the birth of a child.

Structural Factors

Mothers of unplanned children give less time and attention to their infants and demonstrate more negative parenting practices compared with mothers who planned their pregnancies. Unplanned pregnancy is associated with a greater likelihood of perinatal mood problems and reduced maternal and paternal well-being in the postpartum period.

TRANSITIONING

Children from birth through age 8 make multiple transitions across settings, services, and providers. This means children (and their families) often change settings or providers both within and across a particular span of time. Within a span of time, such as a single day or week, children may participate in multiple programs or settings. For example, a child may change programs and locations within a single day, such as a child care program in the morning, and a prekindergarten program in the afternoon. The child may stay in one setting (e.g., public school building), but change programs during the day, attending Head Start in the morning and public preschool in the afternoon. Children often also change settings or services across time. For example, a child may receive child care in a family child care home as an infant and toddler, move to a group child care setting at age 3, and then enter public kindergarten when the child turns 5 years of age.

All of these are examples of what is referred to as *transitioning*. These changes can at times be difficult for children as they often must learn a new set of rules, adjust to different schedules, and interact with different adults and children in a new setting. The goal of good transition planning is to support children in successfully adjusting to new settings, so they can continue to grow, develop, and learn. The time it takes for a child to adjust impacts how quickly the child is able to meaningfully engage in the schedule, activities, and curriculum. This entry provides information about (a) the what of transition, including different components of the transition process and who is responsible for

supporting children and families as they transition; (b) the why of transition, including desired outcomes of good transition planning and reasons that transition planning is an important component of early childhood services; and (c) the how of transition, including simple strategies and activities to support children and families as they move across settings.

The What of Transition

There are a number of ways to support children and their families as they transition between and among various settings and services. To provide this support, it is helpful to first think about two major components of the transition process: preparation and adjustment. Preparation refers to strategies and activities that occur in children's current setting/program to help them navigate the transition process and develop the skills and knowledge they need to be successful in a new setting. Preparing children and families for a transition is the responsibility of the teacher/program currently serving the child, often called the *sending* teacher/program. On the other hand, the *receiving* teacher/program is responsible for supporting the child's adjustment to the new setting. Adjustment refers to the strategies and activities that occur in the child's new setting to support them in acclimating so that they meaningfully engage physically, cognitively, and socially in the environment, curriculum, and classroom routines and activities.

Two other important transition concepts are alignment and continuity. Alignment refers to the degree to which the curriculum, teaching strategies, activities, philosophies, and expectations are similar or congruent across the settings in which children spend time. The greater the misalignment, the harder it may be for the child to adjust to new settings. For example, if the child leaves an environment where the classroom uses a highly structured curriculum and moves to an environment with an emergent curriculum, the child might have difficulty adjusting to changes in curricular expectations and thus, to the new setting. Such adjustment difficulties often pose issues related to

behavior, feelings of safety, and relationships to caregivers or teachers.

Another key concept in transition is continuity. Continuity means the degree to which a child's experiences across settings produce connections that help the child navigate varying expectations within the setting. Continuity is supported in a number of ways, such as staff in each setting sharing appropriate information about children or efforts to systematically connect curriculum across settings. In contrast, discontinuity occurs when the experiences across settings where a child spends time are not well matched, for example, a classroom environment that has established rules and routines versus a classroom where routines and rules change daily or weekly.

Finally, transition practices and strategies include intentional activities used by early childhood professionals to support a child's and family's preparation for and adjustment to a change in settings, services, or programs. These practices and strategies might be implemented at the program, classroom, or individual level. An example at the program level would include transition activities designed to support communication across staff in sending and receiving programs. At a classroom level, activities include those designed to support groups of parents or children such as an open house or sending welcome letters. At the individual level, activities include those tailored to meet the individual needs of a child or family, such as a pretransition home visit to get to know a child and gather information on specific concerns the family may have about the children's upcoming transition.

The Why of Transition

Supporting a child through transitions can result in better academic and social outcomes, as children adjust more quickly and successfully to the new environments, settings, and services. Good transition planning also benefits family members including reducing the stress often associated with concerns about how a child will adjust to a new setting. Family members often worry about such things as will the teacher like my child, will my child make friends, or how will my child handle riding the bus to school?

While transition planning can be beneficial for all young children and their families, in order to meet some children's needs, transition planning is critical. For children with disabilities who receive services under the Individuals with Disabilities Education Act (IDEA), the law requires transition planning for children as they leave early intervention at age 3 (often home-based services) and move to preschool services, most often provided through the public school system. The child's and family's service coordinator facilitates the transition process, including developing a transition plan as part of the child's individualized family service plan (IFSP). Children and their families who receive services through Early Head Start and Head Start also must receive supports for transition, as they move both into and out of the Head Start program.

When transition planning is done well, both families and children benefit. For families, transition planning focuses around four major areas. First, families get the information they need to be actively involved in the transition process. Second, families are able to meaningfully participate in their child's educational experience. Third, families are able to support their child's developmental needs in collaboration with their child's teachers. Fourth, families are able to persistently advocate to ensure that they have the information they need to participate in decision making about the services their child will receive, as well as the ways they might be involved in their child's education and care.

For children, transition planning is successful when children are able to meet three major outcomes. First, after the transition children are able to meaningfully engage in the social (adult and peer interactions) and physical (materials and activities) environments within their new setting. Second, children are able to adapt to the structure (e.g., routines, schedule) and culture (e.g., written and unwritten rules and expectations) within the environment. Third, children continue to grow and learn. While these outcomes could easily describe expectations for any high-quality classroom, the more quickly children are able to engage, adapt, and continue their developmental trajectory, the more likely their success may be related to transition planning efforts, including the degree to which

the sending program was successful in preparing them for their new environments.

The How of Transition

An important role for both sending and receiving teachers is supporting the transition by providing continuity of care across settings. There are a number of practices and strategies that can be implemented to support the transition process. Many of these practices and strategies are low cost and are easily embedded into the general curriculum used by sending and receiving programs.

Starting at the program level, transition can be supported by finding ways to support communication and collaboration between sending and receiving agencies and programs. Strategies that are used at this level include the following:

- teacher visits to the sending or receiving programs to better understand skills and routines that children have or will experience;
- professional development opportunities for teachers that include both sending and receiving program staff;
- sharing information (in person or in writing) about the different programs in the community so teachers are aware of the schedules, approaches, philosophies, curriculum, and so forth across various programs that serve children and families;
- developing processes to align curriculum across early childhood programs; and
- clearly articulating transition timelines and supports/resources available.

At the classroom level, teachers support children and families in both the preparation for and adjustment to new settings by making transparent connections between programs and services. Strategies include the following:

- child and family visits to programs/classrooms before the transition;
- providing an open house before the transition to share information about the program, curriculum, and schedules and to answer parent questions;

- sending welcome letters home to each child and family;
- receiving teachers visit children in their current settings to talk about their new classroom or program;
- developing and sharing video tours of classrooms to share with children and families before they enter a program;
- using phase-in days that allow children to gradually adjust to new settings;
- setting up classrooms at the beginning of the year to more closely replicate settings children have participated in previously; and
- sending information packets home to families to keep communication open on what is happening in the classroom and strategies for supporting their children's adjustment to the new program.

At the individual level, children and families often may benefit from additional supports that are tailored to meet their needs. Strategies to support individualization of transition supports include the following:

- developing an individualized transition plan based on child and family needs;
- sharing information with the receiving teacher about the child, the child's individual needs, and strategies that have been successful in working with that child, which can be accomplished through written packets of information or in a face-to-face meeting;
- individual visits by children and families to new programs prior to their official start in the classroom/program;
- conducting a home visit prior to the transition to identify specific needs; and
- conducting a home visit after the transition to discuss the child's adjustment and identify additional strategies needed by the child or family.

While not an exhaustive list, the practices and strategies above give an idea of the wide variety of ways that transitions can be supported for both the child and the family. It is critical that transition planning is not left to chance; rather it should be thoughtful, purposive, and intentional in terms of

embedding practices as part of the overall services and supports provided by the program.

Guidelines that might help the strategy selection process include the following ideas. Developing a close, positive teacher–child relationship is of utmost importance in supporting the child's long-term success, both academically and socially. Therefore, transition practices that provide the child an opportunity to establish and develop this relationship prior to beginning a new program are important. In addition, the practices and strategies selected for use by a program or teacher should closely align with the program resources, philosophy, and values. At the same time, practices and strategies should be selected based on overall needs of the children and families served in the program or classroom, while allowing for communication and continuity across the early childhood programs available to children and families within the community.

TRANSITIONS AND ROUTINES

The terms *transitions* and *routines* are often linked together to describe dimensions of early childhood care settings and refer to classroom organization and teacher strategies around the use of time and space. Transitions refer to times during the day when children move from one learning activity to another (e.g., from the art center to the manipulative center), or from one designated activity time to another (e.g., from whole group to outdoors). Routines refer to events that happen on a regular and recurring basis within group early care and education settings and are typically associated with task-oriented activities such as greeting and dismissal times as well as personal care routines such as diapering. Routines also include the overall organization of the daily schedule. This entry provides information about the roles of transitions and routines in the everyday lives of children, teachers, and families in early care and education settings.

Overview

Most preschool children in the United States experience some form of outside-the-home care prior to entering kindergarten, and children enrolled in organized child care may spend more than 30 hours a week in those settings. Planning for quality learning experiences often focuses on teacher-directed or child-initiated learning experiences that occur during whole-group, small-group, and

center-based activities. Children, however, can spend up to one-third of their days engaged in everyday routines and transitions outside of those planned “learning” times. By viewing transitions and routines as unique opportunities to establish high-quality teacher–child interactions, early childhood professionals can add richness to their classroom environments through specific strategies and classroom management techniques.

Guiding Children With Transitions and Routines

Many classroom schedules include individual and small and large group activities, outdoor and indoor play, and essential personal care routines. Skilled classroom management involves planning and implementing transition strategies that are compatible with recommendations for best practice as well as the particular purposes and philosophy of the program. Sudden, abrupt changes can be difficult for children, and transitions both assist children in bringing closure to an activity and prepare them to engage in an upcoming portion of their day with minimal disruption.

Transitions are often used to dismiss children from a whole-group activity in an orderly fashion or to safely move between rooms. Transitions provide signals that learning activities or classroom choices are changing. An example of this type of transition is a song that precedes clean-up time. Transitions are also related to guidance through specific learning activities that help children make independent choices, build a sense of classroom community, or wait for turns. Numerous curricular resources provide specific ideas for effective and engaging transitions along with tips for ensuring that transitions complement the daily routine. Transitions are chosen to match the ages and stages of the children involved and can appeal to a variety of learning styles. Transitions can also assist children with specific behavior issues, such as distraction or noncompliance.

Routines provide structure and predictability to the day and contribute to effective guidance through self-care and regulation. Established

routines for greeting children, for example, provide reassurance for children and parents about the consistency of care. Routines for diaper changing or meal preparation ensure that important health and safety regulations are met in an organized fashion. Consistent routines help create a genuine sense of classroom community through repetitive, comforting actions that can soothe both caregiver and child, such as a nap routine that involves reading a story, dimming lights, and playing soft music. Routines give cues to children about expected behaviors. Routines can facilitate cooperation and compliance and reduce power struggles by helping children focus on concrete achievable steps, such as a familiar dressing routine.

Classroom Quality and Culture

A variety of specific classroom environment analysis tools provide guidance on transitions and routines. Recommendations include a well-organized classroom daily schedule, transitional strategies that further the learning goals of the curriculum, and routines that meet required licensing or accreditation standards. Quality classrooms use routines and transitions to establish emotionally secure relationships through teacher–child interactions that convey respect. Research suggests, however, that teacher–child interactions during transitions and routines often consist of directive rather than open-ended conversations. Caregiving routines in particular are not typically characterized by high-quality interactions even though they offer the opportunity for joint-attention activities (focusing on the same event or object) associated with early language development.

Routines engage children in activities that reflect the social and cultural values of a program, such as family-style meals, values about personal space or privacy, or the sharing of toys. Well-planned transitions and routines can further specific learning goals or support a defined philosophy. Montessori and HighScope approaches, for example, include routines and transitions for center choices and cleanup. The Reggio Emilia approach supports a more open daily schedule, adjusted to the interests of the children.

Transitions and routines are an important part of the fabric of everyday life in early care and education settings. The use of appropriate transitions and routines is a key part of teacher training that can transform the utilitarian function of transitions and routines into rich learning experiences that foster high-quality teacher–child relationships.

TRAUMA AND YOUNG CHILDREN

An extraordinary number of young children are exposed to trauma that may impact their development, health, and readiness for school. *Trauma* is an emotionally distressing or painful experience that overwhelms an individual's ability to cope and can result in feelings of despair and hopelessness. Trauma can lead to short- and long-term

negative consequences for an individual's functioning in daily life, health, and well-being. Early childhood education programs play an important role in reducing the impact and prevalence of trauma in young children's lives. This entry will outline the prevalence and types of trauma experienced by young children, describe the impact that these experiences have across the life span, and explain trauma-informed care practices.

Stress and Trauma

An important developmental task in early childhood is learning to cope with everyday stress. Common stressors in the early years include meeting new people, separating from primary caregivers, and encountering unfamiliar situations. In the context of a safe and nurturing environment and supportive relationships, young children learn how to cope with everyday stressors. In doing so, they build resilience and competence that contributes to their successful functioning in life. Sometimes these commonplace stressors are referred to as tolerable stress, in contrast to what is referred to as toxic stress or traumatic stress. When children are exposed to abuse, neglect, or other traumatic experiences, they may experience toxic stress that overwhelms their coping ability. These kinds of traumatic experiences can be particularly harmful to children's health, well-being, and capacity to learn.

Child abuse is one of the most widely recognized types of trauma affecting young children. Very young children are disproportionately affected by abuse and neglect. According to a 2012 report by the U.S. Department of Health and Human Services, 26.8% of child abuse and neglect victims were younger than 3 years old, with the prevalence highest in children less than 1 year old. Neglect was by far the most prevalent form of maltreatment (78.3%), while 18.3% of maltreated children were physically abused, and 9.3% were sexually abused. Children may also experience trauma as a result of exposure to other types of adverse experiences, including community or domestic violence, natural disasters, car accidents, parental substance abuse, and war and political conflict.

The effects of child maltreatment and other forms of trauma are long lasting and cumulative. The landmark 1998 Adverse Childhood Experiences (ACE) study led by Dr. Vincent Felitti found that traumatic childhood experiences have profound and lasting effects on adult health later in life. The ACE study asked participants whether they had been exposed to abuse, household dysfunction, or violence during childhood. More than half of them reported one traumatic experience, and one fourth of them reported two or more traumatic experiences. The study found a direct relationship between the number of adverse experiences in childhood and the risk of health problems in adulthood such as heart disease, substance abuse, diabetes, and premature death.

Impact of Trauma on Young Children

Trauma exposure can interfere with young children's brain development, health, and learning. Children typically achieve numerous developmental milestones during the early childhood years, such as sitting, walking, talking, self-regulating, forming secure attachments, feeding, playing, and learning to share. However, when children are exposed to trauma, they may regress or have difficulty attaining these milestones, often resulting in developmental delays and interfering with learning. Many, but not all, young children exposed to trauma may display one or more symptoms, including extreme temper tantrums, aggression or fearfulness, hypervigilance, or difficulty separating from their caregiver. They can be irritable and anxious, and may either withdraw from others or demonstrate attention-seeking behaviors. Sleep difficulties and nightmares are common, as are digestive issues, low appetite and low weight, and regressive behaviors such as wetting or soiling. Children may also reenact their experience of trauma through play, and may believe that they are to blame for their experience.

Trauma-Informed Care

It is important for professionals who work with young children and their families to understand the

prevalence and impact of trauma, strategies for supporting children exposed to trauma, and what can be done to prevent trauma exposure. Early childhood educators play an important role in young children's lives and help increase children's resilience by providing safe, stable, and nurturing environments and relationships. *Trauma-informed care* is a term that refers to a set of professional practices that support children in feeling safe and secure so they can thrive and heal. For example, maintaining predictable daily routines is important for children who have experienced trauma. Early childhood educators can encourage children to express themselves through dramatic play or expressive arts, create a warm and welcoming physical environment, teach children words to express their feelings, model positive behavior and effective problem-solving skills, and maintain a support network by keeping in regular contact with caregivers and other providers. Most importantly, recognizing that children's challenging behaviors are often adaptive responses to their traumatic experiences helps professionals to approach children and their families from a strengths-based perspective. Practicing self-care and collaborating with others can help professionals who themselves may experience stress from working with traumatized children and their families.

TRUST

Trust is having the belief that someone or something is reliable. It means having feelings of security, certainty, and confidence in the reliability, cooperativeness, and helpfulness of someone or something. This entry provides an overview of trust and how it relates to early childhood education.

Overview

There are three types of trust: (1) Relational trust is having trust in a specific person, (2) generalized trust means trusting people in general, and (3) abstract trust is having trust in systems or abstract entities. The successful building of a trusting relationship between two people leads to the formation of relational trust. Over time, one-on-one trustful relationships result in feelings that are generalized to trusting others. The third type of trust results from a person's experiences with societal systems, such as schools, the police, or medical services, for example. People tend to develop trusting or mistrusting attitudes toward societal systems and abstract entities based on their own individual experiences.

For this entry, the focus is on relational trust. Trust is the foundation of many theories of interpersonal relationships and is often described as the most important component in the development of healthy, successful social and emotional development. Relational-specific trust is an important criterion for successful living because it is fundamental to the

success of all one-on-one human relationships. Any relationship, whether it is between a parent and child, life partners, teacher and student, or supervisor and employee, succeeds or fails depending on the level of trust that has been established between the people involved. Without trust people feel vulnerable, unsure, apprehensive, and unsettled. They hesitate, hold back, and may feel fearful. Without trust, people are inhibited from success in some form or fashion and positive relationships are likely to fail.

Early Childhood Education

John Bowlby's attachment theory and Erik Erikson's psychosocial theory are based on the idea that trusting experiences with other people in early life lay the foundation for psychological well-being and future adult relationships. Bowlby emphasized the importance of caregiver responsiveness to an infant and the development of attachment during the first year of life. He proposed that from the experiences an infant has with a primary caregiver, the infant develops a simple mental relationship model of self and the caregiver. This internal working model of the infant's attachment relationship with the caregiver impacts the child's responses to other people. Thus, a relationship between the infant and caregiver that is marked with positive social interactions, attention to needs, and the building of unconditional attachment leads to the infant's generalized trust of other people.

Through his psychosocial theory, Erikson proposed that the development of a sense of self results from one's relationship with others and the desire to affiliate and to be with other people. This theory proposes eight stages across the life span, each marked by a sense of struggle or crisis that represents different social, cognitive, and biological needs. Each crisis has two possible outcomes with one providing an opportunity for a resolution of the crisis, healthy development, and increased potential for successful social development and the other outcome leading to stagnation or hindrance to positive social and emotional development. Positive resolution of the crisis at each stage depends on whether or not a child's family, society, and culture meet the child's stage-related needs.

The successful resolution of the crisis results in developmental progress. Since the stages of psychosocial theory build on one another, what happens in each preceding stage impacts the current stage as well as future stages.

Trust versus mistrust occurs from birth to 18 months and is the first stage of Erikson's theory. During this stage, infants learn trust through responsive nurturing care. If an infant is not responsively fed, kept engaged in his or her environment, and nurtured, then a sense of mistrust may develop. Trust is central to development during infancy, laying a foundation for feelings of security that underlie the infant's ability to advance in development and successfully proceed to the second stage of psychosocial development, which is autonomy versus shame and doubt. According to psychosocial theory, the issue of trust and mistrust arises at each successive stage of development with the outcome being either negative or positive. Thus, the sense of mistrust can be activated at a later stage of development depending on the child's experiences and circumstances. This has implications for both parenting and early childhood education.

The development of trust and attachment in young children is relevant to early childhood education. Helping young children feel safe and secure through responsive care leads to the successful formation of attachment and feelings of trust. One consideration occurs when a young child enters an early childhood program and children transition from the care of parents to the attention of early care and education teachers. This requires that the child have a positive relationship with the parent and also begin to develop trust with the teacher. Since infants are totally dependent on the care that adults provide, the way that adults respond to a child's needs can facilitate the development of trust. When an early childhood teacher accurately interprets young children's cues and signals, provides warm responsive care, and meets children's emotional and physical needs, a bond of trust is formed and children are able to broaden their trust from parents to teachers and caregivers.

Giving young children time to adjust and to gradually enter into a program provides time for

them to make the transition from home to the early childhood environment. Easing the child in over a period of a few days or a few weeks helps the child to extend trust from the family to the early care and education teacher. Early childhood programs that use a primary caregiving system, where teachers work with small groups of young children, are more conducive to the establishment of attachment and trust between child and early care and education teachers. Primary caregiving systems, where teachers provide a secure base, acknowledge the importance of trust in order to help to facilitate the child's transition to a new environment. When the same teachers interact with and provide care for the same children each day, this continuity supports children in the development of close trusting relationships.

The quality of experiences that young children have in early childhood education programs impacts the development of trust between the child and the caregiver. This has relevance to children's abilities to form future relationships and to make developmental progress not only in the social and emotional processes but also in cognition. Early care and education programs and teachers have a responsibility to provide opportunities for children's successful transition from the family to the caregiver and for the establishment of programming that facilitates the optimal development of trusting relationships between caregivers and young children. Trustful early relationships form a lasting foundation for young children's healthy psychological development and growth.

TYPICAL DEVELOPMENT

Typical development occurs as a child grows and changes according to a predictable sequence and timetable across several integrated, but also distinct developmental domains, or areas of specialization. High-quality early childhood care and education requires professionals whose work is grounded in an understanding of child development because knowing how young children grow and learn informs decisions about curriculum as well as managing and supporting their physical care and emotional well-being. This entry discusses the typical developmental patterns in early childhood for physical, affective, and cognitive development.

Physical development is the domain that centers on growth and refinement of the body's mechanical systems—bones, muscles, tissues, and organs, including brain development and the child's increasing ability to control large and small muscles, or motor skills. The affective domain includes the emergence and development of the child's emotional self, identity, and social awareness and skills. The focus of the cognitive domain is intellectual operations—the use of the brain, including the acquisition of language, thinking, and mental processing skills. Typically developing children achieve milestones such as crawling, walking, and speaking when most other children of the same age are expected to do so. When reaching developmental benchmarks in one or more areas is significantly delayed or absent, a child may be considered to have “special needs.” In early childhood education, the term *developmentally appropriate practice* refers to the idea that care, curriculum, materials, and activities for young children should be planned in consideration of both universal expectations for the general trajectory of development and individual variations from one child to another.

Expected milestones during the early childhood period in each of three major domains for typically developing children include the following:

1. *Physical*: large and small muscle control for locomotion, self-help skills, and the ability to manipulate objects and tools

2. *Affective*: secure attachments with adults, self-concept, identity, self-regulation, and development of healthy peer relationships
3. *Cognitive*: receptive and expressive oral language skills and the ability to integrate physical, affective, and mental processes to initiate and respond to changes in the environment

Developmental Processes

Physical Development

Healthy babies gain weight rapidly; by 1 year of age, most have tripled their birth weight and sprouted many of their primary teeth, which will begin to be replaced by adult teeth at around age 5. The newborn cannot even hold its head erect without adult support, as the baby's head is disproportionately large compared with the rest of the body and compared with the relative size of the head to the body for children, adolescents, and adults. By around age 2, many children have reached half their adult height and have enough language and muscle control to begin toilet training. After this time, the rate of growth begins to slow significantly. Limbs and torso begin to lengthen relative to head size. By age 7, healthy children typically weigh between 35 and 60 pounds and stand between 45 and 51 inches tall. As children near the end of the early childhood period, their body proportions and motor skills are more like those of adults than babies; they will continue to grow about 2 inches per year until the growth spurt that occurs during adolescence.

In general, children's physical development proceeds from the head downward (cephalocaudal) and the center of the body toward the extremities (proximodistal), with increasing control, integration, and refinement of the large and then small muscle groups as time goes on. A baby's brain contains billions of nerve cells (neurons) at birth, but few connections (synapses) between them. During the early childhood period, synapses are created at an astonishing rate, and these synapses enable and facilitate communication between and among the neurons the baby's brain already has. The brain develops distinct areas of function

through a combination of inherited traits and experience, into a complex system metaphorically comparable to an air traffic control center. The brain's various specialized areas control basic body functions (such as breathing), balance and movement, processing of sensory stimuli, development of memory and emotion, spatial awareness, and higher order thinking (executive functioning). The brain is also "plastic" to a certain degree, transferring function from one area to another in the event of damage from an accident, for example. As a child's brain grows, it also becomes more efficient, as unused synaptic connections tend to disappear. Modern brain research continues to point to the critical importance of the early childhood period to brain development.

Many physical movements are controlled by reflexes at birth that gradually fade as the baby's motor system and skills strengthen. Reflexive responses such as sucking, startling, rooting, and gagging are biological protections needed for survival. But within several weeks after birth, the neck and shoulder muscles have strengthened enough for the baby to lift its head, and turn from side to side in response to light or noise. Subsequently, as physical development progresses downward, the infant will gain control and use arm and chest muscles to roll over and raise her trunk from a lying position. When able to control hips and back muscles, the baby will sit up at around 6 months of age. Increasing control of upper and lower legs a few months later will allow the baby to pull up to a standing position by holding on to furniture or an adult for support. Walking begins with feet wide apart and arms raised for balance; the gait narrows and arms lower as control, strength, and coordination increase.

As a child continues to grow, coordination of large muscles and balance improves, and refinement in agility, speed, and control continue to advance as the child's motor skills become more integrated. While infants are born with fine motor skills they need to survive, such as oral structures that enable the baby to suckle, other fine motor skills are largely absent, such as the ability to focus. However, within a few weeks after birth, babies begin to visually track the movement of

objects across their field of vision and acquire the ability to focus on the object, locate it in space, and use their hands and fingers or feet to swat at it, grab for it, and eventually grasp and hold it. As the wrist and hand muscles strengthen, the child acquires more control over the thumb and first finger and fine motor skills advance to being able to hold and control eating utensils, use simple tools like a wooden hammer or large crayon, or stack a set of small blocks. By school age, children are still slightly farsighted, but generally have the fine motor skills necessary to manage tools that require more refined manual control, such as writing implements, scissors, or even a musical instrument. They can engage in such complex and varied physical activities as drawing and writing, gymnastics, ice skating, hammering a nail into a board, or hand sewing. They may engage in vigorous and sometimes rough play, testing the limits of their strength and endurance. They are capable of having highly specialized motor skills and can integrate skills such as running and throwing at the same time.

As a child nears kindergarten and school age, the effects of health habits and quality of medical care can be significantly apparent in terms of their effects on the child's continued physical growth and brain functioning. Inadequate nutrition, untreated illnesses, and excessive or untended tooth decay may result in a child falling significantly short of expected adult size, strength, and mental capacity. While a child's body growth rate, size, and weight are largely determined by genetics and environmental factors, intentional practice and training are often implemented with young children to facilitate development of motor skills.

Affective Development

In the affective domain, children learn to adapt their inherited biological characteristics to different circumstances and control their behavior and interactions according to the socially acceptable norms of their culture and environment. Affective development in the early childhood period proceeds in recognizable stages distinguished by strong internal motivations that when navigated successfully, provide the basis for a healthy self-concept and social

adjustment. Very important during this time are the development of secure attachments, a sense of autonomy, and acquisition of important coping skills such as resilience (stress management) and self-regulation (intentional impulse control). Over time, children's overt and observable responses become less reflexive and centered on physical/survival needs, and more intentional and internalized as they gain language, moral reasoning skills, identity, and awareness of social structures.

Humans are social creatures, and infants and children deprived of social contact can fail to thrive physically, intellectually, and emotionally. As a baby's needs are repeatedly met in an environment with predictable routines, the trusting infant bonds with primary caregivers and learns to wait before crying, beginning the process of self-regulation that is so important to developing an ability to respond to challenges and social expectations. Within a few months, infants display personality characteristics that distinguish them as unique individuals. They can also demonstrate affection and a full range of recognizable emotions including happiness, excitement, anger or irritation, depression, and anxiety.

As children acquire mobility and language, their emotional focus shifts to gaining independence and autonomy and they begin to distinguish themselves as individuals and use language assertively. Between the ages of 3 and 4, children become very interested in social relationships. They use their emerging vocabulary, command of language, and learning by trial and error to negotiate different types of relationships—with adults, siblings, and peers. A sense of belonging, and emerging motivation to be liked, respected, and recognized for accomplishments typically translates to the work ethic and industriousness characteristic of children at the older end of the early childhood period. By the end of the early childhood period, most children also have well-established peer groups and the disposition to use language to negotiate conflicts, express feelings, and describe ideas.

During early childhood, children also acquire their gender identity and begin to understand and associate themselves as members of different social groups and classes. Older infants recognize and

react differently to familiar faces and those of strangers, and early biases or prejudices toward or against different ethnic groups can emerge as early as 18 months. Preschool children may not realize that gender is fixed, and may engage in intensely culturally stereotypical “boy” or “girl” behaviors out of anxiety that their gender is subject to change based on superficial factors.

Cognitive Development

Cognitive development, or mental growth and intellectual functioning, occurs as the brain’s knowledge capacity increases and becomes more efficient, allowing the child to acquire the ability to process, store, and use different kinds of sensory input and information. Brain density and sophistication increase more during the early childhood period than at any other time during the human life span. In as little as two years, the infant who cries as an automated response to hunger acquires the remarkable cognitive ability to understand, produce, and process at least one language and use intentional mental operations to control body systems and behavior. Cognitive development is interpreted in various ways by different theorists, but most agree that children acquire knowledge and understanding by responding and adapting to their environment and experiences.

Jean Piaget, a Swiss psychologist, described cognitive development in a manner generally accepted today as a reasonable explanation for how the brain processes new information, and how the thinking of children can be characterized in distinct stages over time. From birth, knowledge begins to form as bits of information are stored in the mind as “schema.” Infants’ thinking is characterized as “sensorimotor”—processing information primarily as sensory inputs that are reinforced, combined with other schema, and refined through repeated experiences. Physical knowledge develops as children make connections between objects and ideas about how and why they work. As a child is continually exposed to people, objects, and experiences of different kinds, analytical, or “logico-mathematical,” relationships begin to form. A third type of knowledge is characterized by culturally or societally specific conventions (such as the

names of letters) that the child learns to apply according to particular rules.

Each time the brain processes new information, it may recognize the stimulus and assimilate it readily as being consistent with other similar and existing schema. If not, cognitive conflict, or “disequilibrium,” occurs and a more complicated process commences as the brain must rearrange or adapt existing schema to accommodate the new information. For example, if a baby has a large dog at home, and recognizes the sound of the dog’s appearance and bark, when he encounters a small dog at the park, he can’t immediately process it as a dog since it isn’t identical to his dog, but because the new dog also has four legs, a tail, and a similar bark, may tentatively categorize the new animal as a dog as well, adding to his existing concept of what “dog” means. But the baby might also see a small pony and at first label it in his mind as a dog too, until later experiences provide enough information for him to identify more specifically a broad category of animals that includes both pony and dog. Infants are fascinated by new objects and sensations and gradually engage in play behaviors that are primarily focused on repetitive or functional operations on objects. Once a baby has acquired the mental concept of “object permanence,” realizing that things don’t disappear necessarily when out of sight, she will typically enjoy playing peek-a-boo with an adult.

Toddler play and cognitive development is characterized by an interest in things they can move and manipulate. Toddlers engage in parallel play, within proximity of and noticing what other children might be doing, but not necessarily interacting with or initiating collaborative play. The 2- to 3-year-old child is also beginning to use objects for symbolic representation, a necessary achievement for later literacy and mathematics; for example, pushing a small block across the floor and making noises to pretend that it is a car.

From about ages 2 through 7, the way children think becomes “preoperational.” With an already established mental storage system and accumulation of different types of knowledge gained through experience and processing, children use their language, social interactions, and a largely trial-and-error process to begin to move away from “magical” thinking,

and toward a more rational, logical, and organized approach to problem solving. They begin to use what they know and manipulate objects intentionally to increase their understanding of how the real world works. During this time, the typical child will figure out important concepts such as reversibility of processes and conservation, or constancy of quantity despite appearance to the contrary. During this time, children also become less egocentric, realizing that their visual and mental perspectives are not necessarily those of others. This change can be seen in play preferences, as children move from a primary interest in pretend play as 4- and 5-year-olds to increasing interest in organized games and activities with rules. While they will not truly be able to begin solving problems exclusively through mental effort until adolescence, at about age 7, preoperational thinking gives way to operational thinking, when children develop the ability to solve abstract problems, with the continued support of objects and materials they can manipulate to help them work through the mental operations needed to do so.

Another significant cognitive accomplishment and process is the acquisition of language. Most children develop language according to a predictable sequence that culminates eventually in their ability to communicate effectively in various ways. The brain's amazing capacity in even very young children allows them to learn two or more languages simultaneously and switch back and forth between them effortlessly. Long before children can speak, they recognize voices, tone, and inflection, and develop a fascination for words and language.

We produce expressive language through speaking and writing, and receptive language is the means by which we understand others through reading and listening. The components of language include its structure (syntax), meaning (semantics), and functions (pragmatics). Babies use crying, vocalizing, and gestures to communicate. These strategies give way to more systematic babbling, with the first true words typically emerging at about 1 year. As the baby's fine motor skills associated with eating, chewing, and swallowing solid food develop, the child also develops the ability to produce actual speech. Soon the child will use a word to convey a phrase, and combine single words into simple phrases with

rudimentary syntax and inflection (e.g., "Mommy go?" includes a subject/verb combination that conveys a question). Children acquire vocabulary as they begin to name people and objects they can see and touch first, and then the words that represent more abstract connections, such as verbs and modifiers and words that convey feelings or ideas. A typical child's vocabulary increases from about 50 to 100 words at 18 months to about 2,000 words by the time he enters school. By this time, a child also understands about five times the number of words he uses for speech and can also apply environmental clues to figure out words he doesn't understand, a sign of readiness for the symbolic processes of decoding and encoding necessary for learning to read and write.

Humans seem biologically motivated to make sense of unfamiliar information or experiences, so the incentive to learn is great, but because learning and development of language is dependent upon continued exposure to both familiar and new experiences, some young children are considered to be at risk if they reach school age with less experience, language, and cognitive processing ability than others. Many efforts have been made to compensate for perceived experiential deficiencies with early intervention, because of the importance attached to the early childhood period for cognitive development.

U

UNIVERSAL DESIGN FOR LEARNING

Children typically come to school with a range of abilities to see, hear, attend, write, read, count, understand English, transition from one activity to another, manage physical tasks, care for their own needs, engage in learning activities, and remember. These abilities are mediated by the variety of experiences children have had at home and in previous early education and care settings. In the past, many teachers expected their students to conform to a standard of learning and behavior. When it was discovered that a student's abilities were outside what was considered typical, the teacher and other members of the educational team (e.g., occupational therapists, physical therapists, speech and language pathologists, family members) would collaborate to develop strategies and consider adaptations to the curriculum to help the struggling student succeed.

This type of “after the fact” approach was not efficient, especially as increasing numbers of children were fully included in early childhood classroom settings. Educators found that the principle of universal design provided a more desirable approach. Instead of starting with a one-size-fits-all curriculum and making adjustments as needed, universal design for learning (UDL) requires teachers to plan goals, methods, materials, and assessments that provide all learners with equal access to the curriculum right from the start. For

example, instead of providing all students with the same learning activity and expecting them to perform at the same level, the teacher would consider the knowledge, skills, and abilities of the children in her class, and then develop differentiated versions of the activity for her students. She might have adapted scissors available, vary her instructions, allow children flexibility in how and where they are seated, and provide extended time for children needing it.

Roots of Universal Design for Learning

Universal design was first introduced in the field of architecture. Using this principle, architectural visionaries worked to anticipate the needs of and plan physical spaces for the benefit of all people, including individuals with physical and intellectual disabilities. As a result of changes dictated by this principle, many streets now have curb cuts, public buildings are accessible via ramps, aisles are wider, and electronic doors to numerous buildings open as they sense that someone is nearing the entrance. Users discovered that these innovations benefited everyone, not just people with disabilities. For example, not only do curb cuts benefit individuals who use wheelchairs; they also benefit parents pushing baby strollers, teenagers who are skateboarding, and people who use walkers or canes. Doors that open automatically or by pushing a button make it easier for shoppers to reach their car whether they have their arms full

of groceries, use a wheelchair, or need to hold the hand of a young child to keep him safe. In a similar vein, UDL has caused educators to anticipate and plan educational experiences that benefit all learners, including those with physical and intellectual disabilities.

Support for Universal Design for Learning

The implementation of UDL for all learners is supported in legislation and the position statements of major professional organizations such as the National Association for the Education of Young Children (NAEYC) and the Division for Early Childhood (DEC) of the Council for Exceptional Children. The 1997 and 2004 amendments of the Individuals with Disabilities Education Act (IDEA) mandate access to the general education curriculum for children with disabilities. IDEA emphasizes children's right to participate in a challenging curriculum, to the best of their ability. This legislation provides incentives for general and special education teachers and related service providers (e.g., speech and language pathologists, occupational therapists, physical therapists) to collaborate to ensure that each child with special needs has access to and can participate in the same curriculum content as his or her peers.

In 2009, the two major professional associations of early childhood educators, NAEYC and DEC, published a joint position statement, *Early Childhood Inclusion*. The position statement recommends that early educators implement UDL practices to provide multiple and varied formats for instruction and learning so that *every* child has access to optimal learning environments, to home or educational routines and activities, and to the general educational curriculum. In this way, all children can learn regardless of individual, cultural, or linguistic differences.

UDL principles promote access to learning by providing multiple means of engagement, representation, and expression. These multiple means provide flexibility in the curriculum that provides a variety of ways to initiate and sustain each

student's interest and motivation. Early educators must be careful observers so that they can assess not just children's knowledge but also their dispositions and feelings about educational content. Careful observation of young children includes not just watching what they do but also actively listening to what children say and what their actions and body language imply that they want to say. Similarly, early educators learn about children's interests by actively observing their play and interactions with other children, adults, and classroom materials. Emergent curriculum approaches, such as Reggio Emilia, include an understanding that teachers prepare the environments for learners with varied interests and abilities.

Multiple Means of Engagement

Multiple means of engagement refers to the range of ways that children can be motivated, given their different learning styles and challenges, interests, and preferences. Teachers can learn about children's interests and experiences by communicating with family members. Topic-related artifacts, such as gardening tools and live plants, can be added to the environment to increase children's participation. Additionally, as teachers ask questions about these high-interest objects, they facilitate student engagement. Documenting or otherwise featuring students' work in classroom journals or on bulletin boards may facilitate engagement as children reflect on things they did, share observations with peers, and invite family members to look at the documents. Finally, children might use communication cards, sign language, or Braille to engage with their environment.

The project approach supports the ongoing development of curriculum in response to the interests and abilities of children, thereby providing an excellent context for multiple means of engagement. For example, a project on pizza might respond to one child's interest in the machines that prepare the ingredients, while another child might be interested in the process of selling pizza to customers. A child with an intellectual disability

might work at cutting apart and combining play-dough pizza toppings, while a child who is gifted in language might focus on designing menus.

Multiple Means of Representation

Multiple means of representation refers to the variety of ways in which children can gather and share information. A teacher might present information to her students in ways that are responsive to their unique learning styles, abilities, and experiences such as through the use of visual supports (e.g., photos, drawings, felt board characters) while engaging in large group book reading or storytelling.

Emergent curriculum approaches, such as the project approach, can provide early educators with opportunities to consider each child's preferred mode for learning. A teacher can plan multiple ways to investigate a project topic, depending on the individual children in her class. For example, she can make available props and costumes for dramatic play, nonfiction literature, software, Internet sites, visits from guest experts, and field trips. Powerful firsthand experiences such as field trips can provide children who have a range of abilities opportunities to learn in ways that might not be possible had they only seen a picture or even a video about the topic. For example, during a project on pizza, a teacher might provide children with chef apparel, pizza pans, and tools for making pizza. She also can provide children with opportunities to visit a pizza parlor and interview people who work there.

Multiple Means of Action and Expression

Multiple means of action and expression refers to the variety of child responses that demonstrate knowledge or skill across ability levels. In other words, expression refers to the ways in which individuals organize and express their thoughts. Teachers can plan developmentally appropriate opportunities for young children to express themselves in a variety of formats (i.e., raise their hand, vocalize, show a picture card,

use sign language, use an augmentative communication system). Additionally, a teacher might arrange for one child to dictate a story about a trip to the pizza parlor, and she might join another child in the housekeeping area to scaffold his representation of the pizza parlor trip through dramatic play. Media such as glue, tape, paint, cardboard, and clay can be provided to children so they can express their ideas.

Other strategies to support a variety of responses using actions and expression include adding props to the dramatic play and block areas to spark peer interaction and higher level play skills. Teachers might also adapt materials to ensure that all children can use them (e.g., books with popsicle sticks attached to help children turn pages, art smocks with Velcro closures to support independence during painting), or they might pair a socially skilled child with a less skilled peer to support learning and social interaction.

VIOLENCE IN FAMILIES

Violence in the family is a major public health problem as it has significant physical, psychological, and social consequences for children, families, and society. The impact of violence persists beyond the current period of exposure and can affect individuals several years later. Family violence is particularly pernicious as it often occurs behind closed doors and outside the public view leaving many victims unidentified. Moreover, experiencing family violence in childhood significantly increases one's risk for violence as a perpetrator or a victim in later intimate relationships.

Definition

Definitions of family violence vary immensely due to different conceptualizations of which behaviors constitute violence and due to the use of diverse data collection methods. Several dimensions are reflected in definitional variations including family members involved, time frame, nature of exposure, and type and severity of behaviors. Family violence involves at least one family member as a victim and one as a perpetrator, with violence between adult partners referred to as intimate partner violence (IPV), marital or interparental aggression, or domestic violence, and violence between parents and children referred to as child maltreatment, child abuse, or parent-to-child

aggression. Family violence exposure is defined in a variety of time frames, including current or very recent exposure, anytime within the past 12 months, or anytime during the individual's lifetime. The nature of violence exposure refers to the extent of a family member's direct involvement in the violence. This can include being a direct target of aggression or witnessing (e.g., seeing or hearing) aggressive actions toward a family member. Types or categories of family violence may consist of physical abuse, sexual abuse, and emotional or psychological aggression involving threats or demeaning insults. Behaviors can vary widely in severity ranging from pushing, shoving, and slapping to more severe acts such as choking, beating up, or murder. Despite considerable debate about whether corporal punishment is a form of family violence, notable adverse consequences have been associated with corporal punishment.

Prevalence Rates

Family violence is one of the most common and severe negative events youth can experience during childhood. Data on the incidence of family violence can be obtained from legal and social service agencies responding to reports of violence, through nationally representative surveys, or through community studies. Statistics are widely discrepant depending upon the data source, with typically higher prevalence rates obtained through broader sampling procedures utilized in population-based

surveys or community assessments compared with official legal reports. Regardless of source, family violence rates are likely *underestimates* as parents and children may minimize or underreport behaviors that are socially and legally unacceptable.

Data from the National Survey of Children's Exposure to Violence (NatSCEV), an ongoing nationally representative survey, indicate that each year 10% of children ages 0 to 9 are exposed to some form of family violence, with 6% exposed to IPV between parents. Lifetime prevalence rates are substantially higher with 20% of children through age 9 exposed to family violence. Each year more than 1 in 10 children under age 17 are direct targets of child maltreatment including physical abuse and psychological or emotional abuse, with rates doubling over the lifetime to nearly 1 in 5 children (19%). Child maltreatment patterns were similar for boys and girls for physical abuse or neglect; however, psychological abuse was slightly higher for girls than for boys. The most common perpetrators of family violence were fathers or father figures (e.g., stepfathers, cohabitating partners) perpetrating 78% of IPV incidents witnessed by children, although mothers or mother figures as perpetrators were also prevalent (32%). Developmental patterns of children's exposure to violence indicate that witnessing family assaults, including any physical violence or threats, is one of most common victimization experiences for children during both infancy and toddlerhood up to age 5, with a peak of family violence exposure in their preteens and early adolescent years (ages 10 to 13). Patterns of co-occurring family violence—with families experiencing multiple types of violence—are also common, such that families who experience IPV often report child abuse as well.

Summary of Consequences of Children's Exposure to Family Violence

Family violence is associated with impairments in a wide range of domains including children's behavioral and emotional functioning, physical and mental health, psychophysiological regulation, cognitive and academic performance, and peer and

romantic relationships. The nature and extent of impact depends upon the developmental stage of the child. Specifically, for younger children some common sequelae include disruptions in attachment to caregivers, irritability or emotional distress, sleep problems, somatic complaints, fears of being alone, and regression in language and toileting. Externalizing (aggressive, oppositional, and delinquent behaviors) and internalizing (withdrawn, depressed, or anxious behaviors) symptoms are prevalent as are post-traumatic stress symptoms including sleeplessness or nightmares, agitation, and increased arousal.

Family violence also contributes to disruptions in children's physiological regulatory processes that regulate the body's response to and recovery from stress. Both overactivation and underactivation of stress response systems, particularly in the hypothalamic-pituitary-adrenal (HPA) axis responses of infants through school-age youth, have been linked to violence in the home, increasing risk for physical and mental health problems. School-age children also exhibit increased anxiety, have trouble concentrating or paying attention due to intrusive thoughts, and have problems with learning and academic performance. Experiences of self-blame or feelings of guilt are common as children develop more cognitive and emotional awareness about family violence exposure. Peer difficulties, including increased aggression, low levels of social competence, decreased interpersonal sensitivity, and poor empathic abilities are also linked with family violence.

Risk and Protective Factors

Although family violence can adversely affect children in several ways, not all youth experience maladjustment. Many environmental and individual factors have been identified that may protect young children from the negative effects of family violence, or increase their risk for problems. For example, a supportive relationship with a nonviolent parent or other caregiver is a protective resource, as is access to wider social and community support systems. Children's use of emotion-focused coping strategies (e.g., self-soothing, controlling their own

distress) helps buffer adverse effects while use of problem-focused strategies (e.g., intervening in marital violence) is linked to poor outcomes.

Implications

Young children's coping and adaptation following family violence is substantially improved by creating a safe, stable environment with consistency and predictability. Although this is likely a complicated process for children exposed to family violence, those who work with young children and families can make it a priority to help them utilize support from extended family, mental health professionals, teachers, law enforcement, and other social and community groups.

VOCABULARY

Vocabulary refers to both words and their meanings. In early childhood, children develop an expansive understanding of meanings for words they hear others use, and how to use these words to talk with others. Learning vocabulary is critical in early childhood, because the more words (and their meanings) children know, the better they are able to understand or comprehend conversations or text. This knowledge also affects how much they can express their understandings and ideas. Research has shown that children's early vocabulary acquisition predicts their overall academic achievement later on.

Unfortunately, not all children have an equitable chance to learn the Standard English vocabulary that is related to school success. For example, they may have limited access to books, a lack of shared reading time with parents, or limited exposure to advanced words through oral language in their environment. Thus, explicitly facilitating vocabulary learning in early childhood is important to support children's vocabulary acquisition and academic success. This entry provides information about how children develop vocabulary knowledge, why facilitating vocabulary in early childhood classrooms is crucial, and how to facilitate it.

How Children Develop Vocabulary Knowledge

Children learn words and meaning through exposure to words used in their environments, such as

the words used in conversations, in TV shows or movies, and in books that are read to them. The more clues that are available to help children figure out these words' meanings in the contexts in which they are presented, the more children learn about their meanings. In fact, children generally learn about words' meanings over time by being exposed to them in multiple meaningful contexts.

When children are first exposed to a word, they may gain a partial understanding of the word's meaning, such as understanding that *conniving* is something bad. Then, after hearing the word used again they may gain a deeper understanding of its meaning, such as that it is a kind of trickery. Eventually, children will become able to use the word appropriately and explain what it means to others. However, vocabulary learning is idiosyncratic. Sometimes children hear and retain a word used just once in a very meaningful context; other times they may hear a word many times and not attend to its meaning at all. This is related to children's *word consciousness* (i.e., noticing new words and wondering about their meanings), which facilitates learning new words and their meanings.

Why Facilitating Vocabulary Development in Early Childhood Classrooms Is Crucial

Children from varying socioeconomic and linguistic backgrounds encounter vocabulary in different ways within their family environments. They may hear different types of words (e.g., Standard English words versus words in other languages or dialects), different numbers of words (i.e., more verbalization versus less), and differing complexities of word usage (e.g., words embedded in complex sentences with clues to new words' meanings versus words used in less complex ways). This can result in stark differences in the number of Standard English words for which young children know meanings, as well as how much they know about the words' meanings (i.e., their *depth* of knowledge about the meanings for a word).

These differences increase exponentially throughout schooling, creating what many refer to as a gap in vocabulary knowledge. Because

knowing Standard English word meanings affects comprehension of texts and textbooks, as well as orally presented content, the vocabulary gap in turn creates gaps in children's reading comprehension and overall academic success. To close these gaps, the field of early childhood education has paid increasing attention to facilitating vocabulary learning as soon as children enter school.

How to Facilitate Vocabulary Learning in Early Childhood

There are five well-accepted, research-based ways to support vocabulary learning in early childhood: (1) provide exposure to vocabulary words in meaningful contexts, (2) teach vocabulary-learning strategies, (3) directly teach vocabulary meanings, (4) provide opportunities to use newly learned vocabulary, and (5) teach thematically to provide multiple opportunities to learn vocabulary. Teachers should strategically choose an approach that works well for particular words and contexts, but in general, multiple approaches should be integrated for vocabulary instruction. Also, when it is important to learn certain word meanings well, those words should be instructionally revisited using multiple approaches.

Providing Exposure to Vocabulary Words in Meaningful Contexts

There are many ways to expose children to new vocabulary—through reading books, watching TV or movies, and having conversations with them. Picture books are often an excellent source of vocabulary words that are embedded in meaningful contexts. High-quality educational TV shows or movies often offer the same advantages as books, plus animation that may further help to clarify vocabulary meanings, if designed thoughtfully. Adults often use simpler language with children than they do in their writing or conversations with other adults. However, if they recognize the importance of exposing children to new vocabulary, then they can integrate it into their conversations with children in purposeful ways. Using new vocabulary in conversations when discussing a

book or movie, talking during a shared activity or experience, or responding to children's queries provides a highly relevant and meaningful context that can support vocabulary learning.

Generally, children are more likely to learn new words that represent familiar concepts (e.g., *gleeful*, which represents the familiar concept of happiness) through simple exposure, and less likely to learn both words and meanings for new concepts (e.g., *omnivore*) that way. When children encounter new concepts, it is better to teach these words and meanings directly.

Teaching Vocabulary-Learning Strategies

To facilitate children's learning of vocabulary words and their meanings from the variety of contexts in which they encounter them, children must first learn to be word conscious (i.e., to notice new words). Second, they must be able to use any clues about the words' meanings that are provided in these contexts to decipher words' meanings. Many children may need a model and guided practice to facilitate their noticing and using context clues to construct potential meanings for vocabulary words. However, it is important to note that some contexts do not provide any clues that help a child decipher a word's meaning. Thus, children should learn that using context clues is not always possible. Despite this, teaching children to notice available clues and use them to construct relevant meanings for words is an important skill that can improve vocabulary learning.

Overall comprehension of a story or event is also critical to learning vocabulary meanings from context. When children understand the overall context in which a word occurs, they are more likely to decipher a meaning for the word. Thus, helping children understand what is going on in the story aids them in learning new vocabulary.

Directly Teaching Vocabulary Meanings

There are many ways to directly teach vocabulary to children, from quick and simple methods to more complex. First, asking children to repeat a new vocabulary word out loud helps them develop

a memory of the word's sound, or a *phonological imprint*, which facilitates the recall of the word. To help children connect new vocabulary words with their related concepts, pointing to pictures or props that represent the concept, and then saying their name, can help to develop an initial understanding of the word's meaning. To support a slightly more developed understanding of a word's meaning, this can be briefly explained in child-friendly language when it occurs in context. For developing slightly more nuanced understanding, multiple examples of the word's use in context can be presented at the end of an activity, after the brief explanation or pointing and labeling.

Although the methods mentioned take up an increased amount of instructional time, they usually also result in increasing depths of understanding about vocabulary meanings. Choosing a method depends on the depth of vocabulary understanding that is needed, and whether or not additional opportunities to continue to develop understanding of a word's meaning are provided subsequently. Reencountering vocabulary used in context over time reflects the natural learning processes, and when this is possible, more in-depth instruction may not be necessary. However, when understanding a word's meaning is crucial to understanding the activity at hand, a method of instruction that supports deep-enough learning is important.

Vocabulary should be selected for direct instruction of meanings when it (1) reflects a new concept, (2) is important to understanding the story or activity in which it occurs, and (3) is usable by children in their future interactions or activities.

Providing Opportunities to Use Newly Learned Vocabulary

Knowing what a word means when it is heard used in context, or receptive vocabulary knowledge, precedes a child being able to use that word meaningfully himself or herself (i.e., expressive vocabulary knowledge). Once new vocabulary has been presented or taught to children, it is important to build a bridge between receptive and expressive vocabulary knowledge by providing

meaningful contexts in which children can use these newly learned vocabulary words. One way to check children's learning of vocabulary words and their meanings is to ask questions to elicit either their use of a vocabulary word or an explanation of its meaning. This should occur within a meaningful context, such as a story or activity.

Once children have learned a vocabulary word, it is important to engage them in activities in which they can use these words themselves. One popular activity that provides opportunities for children to use newly learned vocabulary meaningfully is the reading of texts that embed the newly learned vocabulary concepts in their illustrations. Another option is having children tell stories related to a curricular theme to provide an opportunity to use newly learned vocabulary, and then having children act them out or having an adult write them down for the children.

To further enhance both vocabulary use and knowledge of words' meanings, concept mapping provides opportunities to use words, discuss their meanings, and represent interrelations between words' meanings in a tactile way. Concept mapping uses physical spaces for representing concept relationships visually. The external representation of vocabulary meanings and how they are related supports children's mental organization of vocabulary words and their meanings, which helps retention. Likewise, inquiry projects provide children with opportunities to use new vocabulary as well as deepen their understandings about the words' meanings through active engagement in meaningful learning contexts.

Teaching Thematically to Provide Multiple Opportunities to Learn Vocabulary

Many successful early childhood vocabulary interventions have used thematic teaching as a way to cycle multiple exposures to vocabulary words targeted in the curriculum. This approach allows for reteaching or reexposing children to words across multiple read-alouds and other classroom activities across the day. Further, as children gain a deeper understanding of the theme, this general understanding helps facilitate children's use of

vocabulary-learning strategies. In turn, this leads to more and deeper vocabulary learning. Thematic teaching also provides opportunities to learn inter-related words and meanings through activities such as concept mapping and inquiry activities.

WALDORF EDUCATION

The first Waldorf education program commenced in 1919, in interwar Germany, after the Waldorf-Astoria cigarette factory in Stuttgart invited Dr. Rudolf Steiner (1861–1925) to help launch an autonomous grade school for the factory’s workers’ children—one as free from state interference as possible. This school, and those that followed, offered a curriculum rich in the arts, heavy on experiential learning, and light on summative testing.

Waldorf pedagogy has its roots in anthroposophy, a holistic philosophy that Steiner developed after contemplating the thinking of Johann Wolfgang von Goethe and Rosicrucian and Theosophist ideas. Often defined as “the wisdom of humankind,” *anthroposophy* offers a path to self-development resting on the assumption that a nonmaterial or spiritual universe interpenetrates and informs the material one.

Anthroposophy is not taught in Waldorf schools but it does permeate Waldorf pedagogy. Indeed, Waldorf teacher training programs offer a core curriculum of anthroposophical material written by Steiner. Moreover, teachers are expected to engage in self-development or “inner work” through artistic pursuits and meditative or spiritual exercises. These are meant to strengthen self-knowledge and thus the ability to be a good role model to children as well as to build intuitive skills and be receptive to new ideas relevant to

one’s students. Teacher training programs also focus on patterns of child development, curricula for different ages, and ways to understand and assist individual children in the task of becoming their embodied, individual, human selves.

Stages of Development

Waldorf education recognizes thinking, feeling, and willing as central to child development. These modes of engagement develop together, but in a staged way: Teachers believe that children grow in 7-year phases, and during each phase, one mode predominates developmentally. Therefore, during different phases of childhood, different pedagogic approaches should dominate too.

In the first 7 years, the will is developing most strongly. It is said to do so through physical activity. Education in the early years should therefore be play based and experiential, not intellectual. Young children’s premature engagement in abstract logic, teachers say, will harden and damage the organism and lead to inflexible thinking in adulthood.

The development of feeling comes to the forefront in the next phase of childhood: ages 7 to 13. To support the development of the feeling mode, lessons during this phase are permeated with the arts.

Between 14 and 21, the development of thinking predominates. Adolescents should be actively engaged in understanding the world in abstract ways.

Facilitating the Flow of Play

Waldorf early childhood educators focus on providing appropriate environments for the will's development—environments that facilitate as much whole-body and make-believe play as possible. Play entailing movement not only builds the will; it allows children to fully develop proprioceptive, balance-related, and gross and fine motor skills—upon which later learning will depend. Sweeping, for example, allows children to master crossing the vertical midline, key to the kind of right-left integration that skillful writing (which comes later) demands. Exercising the capacity for make believe, said to emerge at about age 3, helps pave the way for healthful imaginative and, later, abstract thinking.

Ideally, schools have lots of outdoor space, and as much time as possible is spent outdoors. Children play with natural objects (e.g., stones, stumps, sticks, water, sand) or with props supporting whole-body engagement (e.g., shovels, buckets, wheelbarrows, watering cans). There may be swings or a play structure, but teachers let children develop the strength to master such equipment themselves rather than lifting them onto high bars and the like.

Indoors, rooms have simple wooden furnishings, often with rounded corners and sides that curve and curl; baseboards are cut in undulating patterns. Even the corners of drawing paper are trimmed by teachers to be rounded. Walls are “lazed,” with several thin coats of colored glaze that are lighter at the top, giving the surface an airy, uplifted feeling. For early childhood the preferred color is warm pink or peach. As a whole, a room's billowy curtains, lazed walls, and curves are said to help students maintain healthful expansion and growth. This form of décor thus helps protect against premature bodily hardening and the related ills and rigid thinking that, teachers say, will manifest in adulthood if children are subject to sharp stops, architecturally induced or otherwise.

Much classroom furniture is meant to be moved about and even used for construction, for instance, as children playing freely build houses, boats, riverbanks, and even mythical creatures. Natural objects and simple, hand-crafted toys

without prefabricated media-based story lines are provided according to child age. There may be plain dolls, pinecones, river stones, blocks made from a tree branch, play tools, and wooden food and dishes. The naturalistic containers for such props (e.g., baskets) also may be played with. There may be silk cloths and blankets for draping over upturned chairs. In addition, teachers provide verbal “pictures” of activities to the children with the aim of stimulating and sustaining free-flowing imaginative play (e.g., “It's cold; will you sew a coat?”).

Leveraging Children's Imitative Impulse

Teachers are role models for students who, in early childhood, are said to learn through imitation. First, children imitate attitudes, so that when teachers focus on work they have to do in the classroom, such as cooking oatmeal/porridge for a snack, the children in turn become more focused on their play.

Children imitate actions also. They are said to be drawn to the practical work of the teachers: chopping vegetables for soup; kneading dough for bread; cleaning, sanding, and rewaxing wooden toys. Teachers demonstrate; children follow. Outdoors, children follow teachers in watering plants, sweeping walkways, and so on. Often, the child who is having trouble getting started playing can be drawn successfully into practical work in the interim.

Rhythm

Instead of articulated instructions, early childhood teachers induce order through classroom rhythms. Children are said to gain security through such predictability. Days alternate between quiet, introspective moments or “in-breaths” when children are inwardly concentrated or focused on the teacher, such as during story time, and longer phases of expansive activity or “out-breaths” (children's capacity for an inward focus will increase as they grow). The respiratory terminology reflects teachers' understanding that breathing connects our inner world with the outer world.

Salutogenic Pedagogy

The loving, warm, predictable setting created by Waldorf early childhood educators supports children's successful development, fostering the natural and thereby healthful "unfolding" of that which lives within each child. Keeping children in play helps the body sustain healthful organ growth and expansion. Through whole-body movements, play fosters the child's "incarnation" and sense of being "at home" within his or her body, supporting the sensory-motor integration necessary for learning to write and so on. Play also aids in cultivating the will and the imagination, both necessary precursors for success in grade school and beyond.

WARM AND RESPONSIVE INTERACTIONS

Although successful caregiver–child relationships include many components, the most central component is predictably warm and responsive interactions—reactions that are consistent, prompt, contingent, appropriate, and in support of the child's needs. The ability of a caregiver to interact with the child in predictably warm, responsive ways is crucial because the moment-to-moment interactions accumulate to shape the child's expectations, behaviors, schemas, and developmental progress. Underlying the formation of warm, positive relationships is layer upon layer of sensitive, responsive interactions over some extended period of time.

Historical Background

Attempts to parse out the sequences, functions, and outcomes of caregiver–child interactions are relatively new, beginning perhaps with William James, who, in the late 1800s, studied innate social response systems. Psychoanalytic theorists from the 1940s onward, through an object-relations prism, believed that social mirroring shaped children's self-concepts, including their perceived worthiness for love and a later ability to show kindness to others. Developmental psycholinguists beginning in the 1960s advanced understandings about the importance of infants' prelinguistic communications and how caregivers' ability to correctly interpret and respond in a preverbal dialogue predisposes the child to language acquisition. In the 1970s and 1980s, social mediation researchers noted that sensitive caregivers complement and extend children's capacities in the zone of proximal development, so the child develops cognitively and in culturally meaningful ways. In each of these frameworks, theorists considered early social interactions central to children's emotional, social, cognitive, and language development.

John Bowlby and Mary Ainsworth raised the importance of caregiver–child interactions to signature salience through their work on attachment

theory from the 1950s to 1980s. The World Health Organization (WHO) commissioned Bowlby, working in London, to study the mental health of orphans in the wake of World War II and published the seminal monograph in 1951. It revealed the deleterious effects of institutionalization on young children, showing how interaction-deprived children go through phases of protest, despair, and detachment. Bowlby's conclusion was that in order to develop normally, "the infant and young child should experience a warm, intimate and continuous relationship with his mother (or mother substitute) in which both find satisfaction and enjoyment."

He and early collaborator Ainsworth, whom he hired for his research unit examining the effects of separation on personality development, jointly observed that it is through the quality of interactions within a relationship that young children develop expectations about how people would behave toward them, in turn shaping children's responses in a self-perpetuating cycle. Through work in Uganda and later Baltimore, Ainsworth further developed the sensitivity-responsivity theory of attachment, wherein children are observed to have secure attachments with caregivers who interact in warm, caring, sensitive, and responsive ways, and insecure (insecure-avoidant or insecure-anxious) or disorganized attachments when caregivers seem inconsistent, rejecting, detached, or frightening.

Much cross-cultural evidence supports the substance of attachment theory. Critics, however, find that attachment theory embodies too narrow a view of children's interpersonal experiences and fails to take adequate account of children's temperaments. They also suggest that there is insufficient evidence supporting the specific dimensions of interactions that contribute to attachment classifications.

Defining Warm and Responsive Interactions

Although critics say that the concept of warm and responsive interactions is fuzzy and hard to operationalize, others say it is easy to recognize when one sees it. Researchers have observed that positive

interactions contain and convey mutual engagement, matched behaviors, and synchronized emotions. Adults express availability, affection, empathy, encouragement, support, and guidance, and children, depending on developmental status, may display attention, a state of calm, engagement, brightening, social referencing, and delight. Children in positive-interaction relationships begin to coordinate awareness and interchanges with the adult and have a secure base from which to explore the environment and interact with others—thus building social-emotional and cognitive foundations on which further development can occur.

Sensitivity and Responsiveness

Researchers have identified two fundamental qualities that are central to positive interactions: sensitivity and responsiveness. These abilities enable an adult to recognize and correctly interpret a child's signals, and respond in synchronous ways that meet the child's needs.

Sensitivity has emerged across cultures and population types as a critical dimension of positive interactions. An adult who is sensitive is capable of seeing the child as separate from herself and seeing the world from the child's point of view. It allows an adult to recognize basic signals for what they are, such as fatigue, distress, or hunger, rather than imposing a self-oriented or norm-referenced interpretation. For example, an attentive caregiver realizes a baby's fussiness is because he is hungry, regardless of the fact that he just ate an hour ago or that it is "the wrong time" for a meal.

Responsiveness refers to how promptly and appropriately the caregiver reacts to the child's signals or communications. It captures how attuned and reciprocal a relationship is. Responsive adults have an empathic awareness of how a child wants to be related to in the moment and are able to carry that out appropriately. Responsiveness contains constructs of predictability (the adult can be relied upon to react empathically), contingency (the adult responds according to the child's signals), and emotional availability and positivity (the child perceives that the adult wants to engage with the child and will do so with warmth, affection, and support).

Mary Ainsworth and colleagues cited four components related to sensitivity and responsiveness:

1. Awareness of signals—which requires an appropriate physical proximity to the child
2. Accurate interpretation of signals—which requires emotional awareness and ability of the caregiver to not project, interfere, or deny what the signal means, but rather to be attuned, empathic, and emotionally available
3. Appropriate responses to child communications—which requires developmentally appropriate reactions, such as picking up and comforting a distressed infant or letting a preschooler run off and play with a friend
4. Prompt responses—the adult’s reaction is perceived to be contingent on the child’s communication and supportive to the child

An important contribution of sensitive, responsive caregiving is the ability to refrain from interactions when the child needs a recovery period or independence.

Negative Interactions

Conversely, negative, negligent, and harsh interactions are likewise recognizable and useful as a comparison. In negative interactions, an adult may

- scowl, speak with annoyance or hostility, shout, criticize, shame, blame, be sarcastic, or call the child names;
- fail to respond to the child’s vocalizations, engage with the child, or make eye contact; ignore the child eating, dressing, or playing; and mainly focuses on other people or activities, such as other adults or electronic devices;
- be physically absent or fail to provide adequate supervision;
- not show enthusiasm or joy with the child, fail to take pride in accomplishments, or is businesslike or mechanical;
- be intrusive and overly controlling, perhaps hurrying children, overstimulating them, or

forbidding them to do many activities even when they are developmentally appropriate; or

- be physically harsh, such as grabbing, hitting, or pinching children.

Children’s Signals and Reactions

Interactions by definition are bidirectional, and children can play an important part in the quality of interactions. A child’s ability to express emotional states in a clear and consistent way impacts adults’ interpretation and responsiveness. For example, an infant who cries when hungry and smiles when happy is easier for an adult to understand than an inconsistent infant. An underdeveloped infant who perhaps has an immature neurophysiological system may have erratic states and less synchronized motor systems; he may smile one minute and be fretful the next without obvious triggers. Motivated and skilled adults can have warm, responsive interactions with any child, but it may take more work with less developed and less skilled children.

In general, as infants grow into toddlers and children, they display affect that mirrors the state of their interactions. A child who typically experiences responsive interactions readily makes eye contact, attempts to engage and imitate the person, anticipates engagement with smiles and brightening, wants to be physically close to the adult, expects help if a problem arises, initiates communication, and expects a response. The child wants to share a positive or negative experience, uses the adult as a secure base and looks to the adult for guidance and feedback, is distressed by separation, and may be wary around strangers. In contrast, a child who experiences negative interactions whimpers, shows anger, anxiety, avoidance, or other negative emotions and can be passive, detached, nonsocial, or mechanical. Even in the presence of responsive adults, interaction-deprived infants are less attractive to adults, cry more and more monotonously, and elicit less positive feedback from caregivers.

Functions and Mechanisms

Robert Bradley and Bettye Caldwell in 1995 identified the following five interconnected functions addressed by caregiver–child interactions:

1. Sustenance: provision of food, shelter, and basic biological support
2. Stimulation: engaging with a child; providing appropriate types of experiences and amounts of information; and fostering cognitive growth, curiosity, and a desire to explore and learn
3. Support: meeting social and emotional needs and reinforcing goal-directed behaviors
4. Structure: differentiating inputs depending on a child's ability levels and needs, scaffolding, and regulating stimulation so that each child experiences a good "fit" with various inputs
5. Surveillance: keeping track of the child's whereabouts and activities and ensuring a reasonably safe environment through supervision

The interactions also serve as mechanisms that impact children's development, including (a) priming of a child's responses to the environment in neurophysiological and psychological ways (e.g., repeated negative interactions require a child to self-regulate to mitigate negative affect), and (b) development of internal working models or mental representations—the child learns to expect all adults to be uncaring and stops seeking assistance or learns to expect warmth and assistance and therefore solicits interaction. These mechanisms lead to self-reinforcing chains of consequences.

Interactions in the Classroom

In most cultures, more than one adult has a loving relationship with a child. Teacher figures, whether in formal programs like a classroom or informal arrangements like kith and kin care, play an influential role in many young children's lives. The more experience the child has with positive interactions, the deeper the child's sense of security, self-worth, and empathy.

The quality of teacher–child interactions has been noted as central to program quality, child development, and outcomes associated with program experiences. For example, the National Association for the Education of Young Children

(NAEYC) from the 1980s onward has articulated that teacher–child relationships are at the heart of program quality and child outcomes, noting that positive relationships based on positive interactions are essential for learning and development, development of personal responsibility, self-regulation, and constructive interactions with others, all of which relate to classroom and general functioning.

Many organizations work to support teachers of young children to have warm, responsive teacher–child interactions, such as the Center on the Social and Emotional Foundations for Early Learning (CSEFEL), the Center for Advanced Study of Teaching and Learning (CASTL), the National Training Institute for Child Care Health Consultants housed at the University of North Carolina at Chapel Hill, UNICEF, the World Bank, Save the Children, World Vision, and Plan International, to name a few.

Associated Child Outcomes

The type of interactions children experience with important caregivers cumulatively shape their development in every important domain.

Brain Development

Warm, responsive interactions play a uniquely powerful role in caregiver–child relationships because they partially determine how a child's brain develops. The architecture of the brain takes form in response to the presence or absence of expected social inputs, among other things, and in response to the quality of those inputs. Synapses develop in and solidify with repeated use, and brains exposed to repeated positive interactions develop and strengthen pathways built upon those interactions. Children seek the types of experiences they have come to expect based on the most used and more developed neural pathways, thereby reinforcing early connections.

Survival and Physical Health

Infants who have responsive caregivers are simply more likely to live beyond the first month of life. Caregivers are the gatekeepers of children's health as they determine the amount and type of nutrition

infants take in; physical comfort experienced; likelihood of illness and injury; and the initial emotional support and assistance infants receive, such as being smiled at, held, and talked to. Infants of less sensitive and responsive parents are more likely to have low birth weight, show failure to thrive, be malnourished or stunted, experience recurrent infections, and be subject to neglect and abuse.

In contrast, responsive caregivers provide adequate nourishment, protection from toxins and dangers, physical warmth and safety, and interaction, allowing children to survive, gain weight, and grow. Growth at age 2, for example, is predicted by ratings of maternal warmth and responsiveness at 9 months. Children who have sensitive caregivers are also more likely to experience medical checkups and receive immunizations than others, and more likely to have speedy recoveries from illness. They are more likely to have predictable daily routines that promote a sense of security and to experience less stress than children cared for by less responsive caregivers.

Social and Emotional Well-Being

Children who typically experience positive interactions have healthy relationships with their primary caregivers. They are likely to become people who have insight into others' feelings, needs, and thoughts, forming a foundation for cooperation and conscientious behaviors. They learn how to share, take turns, and self-regulate. They play well with others, develop friendships, and show fewer problem behaviors and higher social skills than other children. They are less likely to experience peer rejection, shyness, and externalizing behaviors such as aggression and acting out. Caregiver responsiveness associates with children's sense of self-competence and self-worth, interest in exploring, communication skills, and sense of security. As adults, they are more likely to develop warm, responsive relationships with other adults and be more confident and assertive.

Cognitive Development

Interaction quality impacts cognitive growth through exploration and stimulation experiences.

Children's experiences with warm, responsive interactions correlate highly with cognitive skills and academic achievement. Teacher displays of strong emotional support to students relate to growth in students' phonological awareness, reading ability, and math achievement, for example. At-risk young children display fewer attention and academic problems than similar peers if they have strong emotional support from teachers. At-risk children with less supportive teachers show lower achievement levels and more conflict with teachers. More generally, children having extended experiences with positive interactions with parents or teachers, compared with others, have better concentration and show better language development, higher school readiness ratings, better performance on IQ testing, greater engagement and achievement in school, and enhanced thinking and reasoning skills.

In the Absence of Warm, Responsive Interactions

Compelling evidence for the need for positive interactions is seen in children who do not experience them—those who are deprived of extended loving care for some reason. Reasons include institutionalization, external conditions like extreme poverty or low adult education that hinder caregivers' capacity to be sensitive and responsive, internal conditions like maternal depression, or triggers such as child impairment that challenge caregivers.

Institutionalized infants are often listless, emaciated, relatively immobile, quiet, and unresponsive; seem unhappy; have poor sucking responses; lack appetite; sleep fitfully; fail to gain weight adequately; are withdrawn—and have higher mortality rates. They often become children who show indiscriminate attachment and friendliness, clinginess, and attention-seeking behaviors. Early institutional care correlates with higher than average risk of serious infectious illness, delayed language development, and reduced cognitive abilities. These children become adults who are more likely than others to live in poverty, have psychological impairments, and have difficulty finding and keeping employment.

Measuring Interaction Quality

Despite the theoretical importance of and empirical support for the importance of caregiver–child interactions, there are relatively few measures that focus specifically on interaction quality. One of the early research methods for quantifying interaction quality between caregivers and children was Ainsworth’s Strange Situation, which she used to decode how securely attached a child felt to the primary caregiver.

In more contemporary research, the Home Observation for Measurement of the Environment (HOME) Inventory and the Infant/Toddler Environment Rating Scale/Early Childhood Environment Rating Scale (ITERS/ECERS) are widely used measures. However, both capture overall quality of the environment and include many constructs in addition to caregiver–child interaction quality, such as the safety and furnishings of the physical facility, the availability of toys and materials, staff support, and so forth; thus, it can be inappropriate to equate high scores with high-quality interactions without examining subscores. Other measures include the Classroom Assessment Scoring System, the Caregiver Interaction Scale, and the Caregiver–Child Social/Emotional and Relationship Rating Scale.

Interactions Matter Across the Lifespan

The more skilled is the adult in his or her interaction abilities, the more solid are a child’s chances not only of survival but also of healthy physical growth, developmental progress, and achievement. Although brain development provides unique opportunities for early childhood interactions to shape child outcomes, positive interactions matter across the lifespan and impact is not limited to the window provided in infancy or early childhood. People who do not experience sufficient warm, responsive interactions as infants or young children still benefit strongly from repeated loving interactions later in childhood and into adulthood if they occur in the context of significant relationships that extend over time. An overarching outcome of these interactions, according to Eleanor

Maccoby, is that children become competent, caring adults who function well in society. They are then able to provide sensitive and responsive care to the children they care for and teach as adults, extending the benefits across generations.

WELLNESS MODEL FOR YOUNG CHILDREN AND FAMILIES

According to the World Health Organization, health is “a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity.” Wellness is much more than

physical health; it is essentially an ecological construct, encompassing the multileveled influences, both internal and external, within which an individual's lived experience unfolds.

Over the past decade, there has been growing awareness among parents, teachers, social service providers, and medical and mental health professionals of the primacy of the young child's wellness in predicting prospects for healthy development and functioning in the long term. This awareness has been coupled with the recognition that the wellness of young children and the wellness of families are inextricably intertwined. Family experiences and resources shape the opportunities for wellness promotion that are available to young children, and lay the foundation for young children's healthy development. Grounded in a holistic perspective, the wellness model highlights the many interwoven personal, familial, social, cultural, and economic factors that combine interactively to define the well-being of children and their families.

The model transforms traditional conceptions of wellness as simply the absence of disease or medical problems into proactive models for promoting and sustaining well-being. The wellness model places emphasis less on specific behaviors and more on general lifestyle goals and choices, and most important, it affirms the efficacy of children and families to make choices that promote wellness. The model affirms that wellness is a social good and that a healthy and just society is defined by its capacity and commitment to affording all its citizens opportunities to grow and develop in ways that fulfill their potential for well-being.

Challenges to Wellness for Young Children and Families

Evidence has mounted regarding challenges to young children's well-being across many domains. Childhood obesity has been described as an epidemic, rates of associated disorders such as early onset diabetes have grown substantially, and food insecurity among families with young children has risen to record levels. Reports of stress-related symptoms in young children, including anxiety, depression, and post-traumatic stress disorder,

also have increased. Problems with emotional regulation and behavioral control are increasingly prevalent as well. A recurring finding in each of these areas is comorbidity—problems generally occur in multiple areas, rather than only in one. This comorbidity confirms the ecological nature of wellness as emerging from the ongoing intersections of multiple internal and external influences on young children and families. When a young child is sick or troubled, the functioning of the family system is compromised by the demands placed on it by the child's condition. Conversely, constraints on families' socioemotional energy and their access to educational, economic, vocational, and community resources affect the wellness promoting options available to their young children. For this reason, efforts to improve long-term outcomes for young children and their families have begun to emphasize more holistic approaches. The United Kingdom, for example, has created a new professional certification, early years professional (EYP), that encompasses studies in child development, health, education, and social welfare.

Home Contexts of Wellness for Young Children and Families

The ongoing, everyday routines and interactions of young children and families in their homes shape and also embody their well-being. These shared early experiences have long-lasting impact on patterns of eating, physical activity, and emotional responsiveness and expression. They frame children's beliefs about specific health behaviors as well as their personal efficacy to make choices that promote wellness.

The long-term positive impact of three common household routines on child well-being was noted by Sarah E. Anderson and Robert C. Whitaker, who found that preschool-age children (1) exposed to regularly eating the evening meal as a family, (2) obtaining adequate nighttime sleep, and (3) having limited screen-viewing time were 40% less likely to be obese than those with none of these routines. While lasting on average only 20 minutes, family mealtime has been

described by Barbara H. Fiese and Marlene Schwartz as a “densely packed event” that has powerful developmental impact from early childhood through adolescence. For example, Dianne Neumark-Sztainer, Melanie Wall, Mary Story, and Jayne Fulkerson (2004) reported frequent family meals at home promote improved child nutrition and language development, and decrease the risk of eating disorders among adolescent girls.

The long-term influence of family experiences at home on the socioemotional dimensions of well-being has also been extensively documented. Patricia Kerig, Amanda Ludlow, and Charles Wenar (2012) highlight ways in which parental psychopathology is associated with compromised emotional development and general well-being in their children. Children exposed to harsh and punitive parental practices are more likely to manifest difficulties with emotional regulation and behavioral control, which frequently are associated with decreased academic performance. These early problems often are precursors of patterns of disruptive behavior and diminished academic achievement lasting through adolescence or beyond.

Links Between Wellness and Educational Achievement

Beyond the ongoing transactional processes between physical, cognitive, emotional, and social development and learning, wellness is connected to academic achievement through its links to school readiness. Wellness encompasses the “physical, cognitive, social, and emotional competence” cited by the National Association for the Education of Young Children (NAEYC) to define school readiness. NAEYC emphasizes the ecological nature of wellness, stating, “*readiness* includes ready children, ready families, ready communities, ready early care and education, and ready schools.” Wellness enables children to come to school with positive feelings, comfortable in their bodies and secure in their emotions and social surroundings. Operating from this safe base, children have the foundation for positive attitudes toward learning.

As the pace of family life has accelerated, family routines that support both wellness and school

performance such as regular patterns for eating, shared book reading, and sleeping have been eroded, and the levels of stress experienced by young children and their families have risen, with widespread negative consequences. Magdalena Janus and Eric Duku found that poor parent and child health are both related to lower school performance, especially for children living in poverty. Barbara H. Fiese, Craig Gundersen, Brenda Koester, and LaTesha Washington documented associations between food insecurity and children's short- and long-term physical health, psychosocial well-being, and academic achievement, and Marcus B. Weaver-Hightower described "nutritional confounding" of children's test performance due to the effects of their health status and general well-being.

Promoting Wellness for Young Children and Families

Growing public concern about child health issues is reflected in Head Start/Early Start's Healthy Start resources, which emphasize connections between children's wellness and their readiness to learn, as well as in First Lady Michelle Obama's initiative Let's Move!, designed to encourage healthy nutrition and physical activity regimens. Although parents and teachers agree on the importance of wellness, many report feeling unprepared to address it with young children.

Home and school are the natural and primary contexts for promoting wellness for young children and their families. Wellness issues are the focus of many of the interactions between young children and their caregivers in these settings, and the responses that children receive to their questions and demands shape their understanding of what it means to "feel okay," "eat well," and "make good choices." Helen L. Johnson and Leigh Shebanie McCallen identified key principles to guide parents' and teachers' efforts to promote child wellness:

- Maintaining strong partnerships between families and schools ensures that children receive consistent messages that are respectful and inclusive.

- Framing wellness messages in a positive tone offers children information about behaviors that will support their wellness.
- Establishing explicitly health-oriented caregiving environments and processes supports children's capacity to make choices that will protect and promote their own well-being.

WORK AND FAMILIES

The Bureau of Labor Statistics reports that in 2014, of 80.9 million families in the United States, approximately 80% have at least one employed member. A 2014 American Psychological Association study found that 60% of Americans perceived work as a “significant” or “very significant” source of stress. Social scientists refer to the relationship between work and family as the work–family interface. The spillover-crossover model has been used to examine the impact of the work domain on the home domain and the transference of work-related emotions from the employee to others at home and vice versa. The work–family and family–work enrichment models take into account the positive factors in one domain that enhance performance in the other. Positive well-being in either work or family facilitates integration and balance of both domains. Negative well-being can also contribute to segmentation and conflict between work and family.

This entry draws upon Urie Bronfenbrenner’s bioecological model to examine individual, meso-system, exosystem, and macrosystem relationships between work and family. While the literature on work and families is vast, the entry focuses on key findings vis-à-vis the bioecological model. It considers individual characteristics (e.g., gender, family composition, ethnicity, and socioeconomic status), mesosystem-level constructs (e.g., positive and negative work–family spillover, work enrichment, and health implications), and macrosystem factors (e.g., cultural influences, organizational and government policies).

Bronfenbrenner’s Bioecological Model

In recent years, social scientists have become increasingly concerned with the effects of social contexts on human development. This interest has been motivated, in part, by the emergence of theoretical perspectives emphasizing the impact of individual and contextual factors (e.g., gender, families, work) on development. The bioecological model emphasizes context; individuals and families are influenced by multiple contexts, as well as the relations among these contexts and how these interactions change over time. Also included is the concept of bidirectional effects and person-context interactions. Thus, the work–family connection can be viewed via the interaction of person, process, context, and time.

The bioecological model can be described as a series of concentric circles drawn around an individual. The circles each represent different systems that influence the individual’s development. Individual characteristics, such as a person’s gender, are considered at the core of the model. The innermost circle consists of an individual’s “microsystem,” those environments with which an individual interacts directly, such as immediate family and school or work environments. The next largest circle, the “mesosystem,” is conceptualized as interactions between microsystems, such as interaction between family and work environments. The next system, the “exosystem,” includes environments where the individual may not directly interact, but still exert influence on the individual. The exosystem can also be thought of as the microsystem of someone in the individual’s microsystem (e.g., a spouse’s or parent’s workplace). The “macrosystem,” or outermost circle of the model, encompasses global influences on an individual, such as government policies (e.g., family leave time), media, and cultural influences. The “chronosystem” is inherent across all systems within the model, indicating changes that occur during the passage of time. These temporal elements could include the birth of a child, for example, or a parent changing jobs because of incompatibility with family life.

Individual-Level Variables

Variations at the level of the individual, at the center of Bronfenbrenner's model, include gender, temperament, ethnicity, and socioeconomic status. Traditionally, greater responsibility for caregiving fell to women, and work-to-family conflict affected life satisfaction to a greater degree for women compared to men. A meta-analysis from the late 1990s reviewed decades of studies and concluded that life and job satisfaction for men and women are affected by both type and direction of these competing role dynamics. In the last decade, competing gender role dynamics have been equalizing and including fathers' balance of work and family life. Many studies regarding family composition and work examine two-parent middle-class households. Studies that have compared work stress between dual-parent households and single-parent households have identified even greater conflict between work and family for single-mother households. Since the percentage of single-father households remains small, little is known about them. In families with lower income, workers tend to have greater strains, increasing risk of injury and stress and less scheduling flexibility to support a work-life balance. Racial and ethnic minorities make up an increasing share of the U.S. labor force, but are underrepresented in work and family literature, so our knowledge base remains limited. Family structure and belief systems of minority groups likely create greater variation in the work-family interface than is available in our current understanding.

Mesosystem and Exosystem Levels

A review of recent research in work and family identified three themes: (1) external job demands and children's experiences inside families (exosystem), (2) nature and management of boundaries between work and family (mesosystem), and (3) linking experiences within families to both proximal (local supports) and distal (cultural norms) environmental influences (mesosystem and macrosystem). These underlying themes support the importance of identifying important work-family interactions via the bioecological model.

The spillover-crossover model emphasizes the impact of work on the home domain and vice versa through the transfer of well-being. The ways that well-being can be transferred is categorized into crossover and spillover. Spillover concerns the positive or negative well-being at the individual level across domains of work and family. Constraints that can cause interrole conflicts can be time based (e.g., not enough time to accomplish demands of both roles), behavior based (e.g., requirements of one domain interfere with expectations in the other), or strain based (e.g., pressure in one domain makes it difficult to engage in the other). An example of work-to-family spillover is an employee who works extended hours, compromising leisure time with family. Family-to-work spillover occurs where the pressures of a family role have an unfavorable impact at work. For example, an employee caring for an ill child may be chronically late or absent at work. Crossover, which demonstrates exosystem interaction, is when the transmission of well-being takes place between closely related persons through social interactions. An example is a parent who exhibits anger toward family members as a result of work stress.

Work-family enrichment, also referred to as work-family facilitation, refers to a process at the work-life interface where participation in one role (e.g., work) increases the quality or performance of the other role (e.g., family). The primary focus is on positive interface between work and family. Work-family enrichment can occur when work contributes to skill growth or positive mood changes that then have positive effects on family. A positive work environment, including points such as scheduling flexibility, job satisfaction, support from colleagues, and mastery of skills, contributes positively to work-family enrichment. Family-work enrichment can occur when participation in family roles (e.g., confidence as a parent) has a positive impact on work performance.

Boundaries are guidelines or rules that a person identifies as reasonable interactions with others or the environment. Work and family boundaries can control spillover from one domain to the other. Boundaries run on a continuum with segmentation (compartmentalizing work and family) on one end,

and integration (combining work and family roles) on the other. Integrators tend to keep weak boundaries (e.g., responding to electronic mail or accessing databases after work hours). People who fall in the middle move back and forth between integrating and segmenting their work and family domains (e.g., a retail worker who works long hours during a holiday season, neglecting family responsibilities, but then segments work and family time effectively other times of year). People who segment work and family have strong boundaries and consistently resist temptations to blend the work and family (e.g., resisting messages sent after work hours). Boundary management styles enhance an understanding of work and family interface at the mesosystem and exosystem levels.

Family relationships are influenced by the broader social environment. As an example of the influence of the exosystem, work environment can impact nonemployee members of the family. When an employee has strains at work, it can have a negative impact on both parenting and partner relationships. Parenting has been categorized into two dimensions: warmth (responsiveness) and monitoring (consistency). Children generally benefit most from high warmth and monitoring. Higher work conflict is associated with lower parenting warmth and lower monitoring, putting children at risk for being negatively influenced by parental work environments. Conflict in couples is linked to lower parent mental health as well as more negative parent-child interactions and child outcomes.

Workplace strains can manifest as health outcomes that impact both the employee and the employee's family members. Negative behaviors in the workplace have been linked to the health of both employee and spouse. Stress in the workplace has been commonly associated with employee depression, anxiety, and physical symptoms. Research in the last decade has examined men's job demands and found high work duties and emotional demands were positively associated with partner's reports of work-to-family conflict. Men's work-to-family conflict was negatively related to quality of spousal interactions; men exhibited decreased social support and increased social undermining. These connections were linked with

women's ill health, especially depression and physical complaints. High-conflict and emotionally demanding positions at work are linked with poor relationship quality and negative health outcomes. In contrast, jobs with both structural and psychosocial support have positive influences on employee well-being, engagement, and motivation.

Macrosystem Level

Effective government policies have been found to both reduce negative work-family spillover and enhance work-life integration. Caregiving conflict is one the greatest challenges of balancing work and family. Caregiving can affect work time, for example, if an employee takes personal leave due to illness or the care of others such as aging parents or children. The Family and Medical Leave Act (FMLA) of 1993 requires covered employers to provide job-protected and unpaid leave for qualified medical and family reasons. Research supports the importance of policies like FMLA to alleviate the stress of losing one's job as a result of an extended leave-of-absence for medical or family reasons. Such policies support the long-term commitment and work productivity of employees. The FMLA has been critiqued because the policy does not require paid leave. Paid leave is a decision left up to individual states and only a small fraction offer it. In a comparison of family leave policies worldwide, the United States falls short. The cost of raising children in the United States is tremendous; not having a paid leave option creates even more financial challenges for families who depend on dual wages to make ends meet.

Even though not required by law, there are many employer strategies to support their employees such as on-site child care, employee assistance programs (EAPs), paid family leave options, and nontraditional work schedules. Such programs can increase the perception of work-family gains and decrease work-family strains. Longitudinal research indicates that perceived work-family strains are associated with decreased work commitment, while perceived work-family gains are associated with increased work commitment. Research has also demonstrated links between

work–life balance employer strategies and organizational performance. Institutes like the Work, Family & Health Network recognize the mutual benefits of increasing employees' sense of control over their own time, improving supervisor support for work and family balance, and changing the culture to focus on work that matters most for the business. Even though employer policies rooted in these ideas have demonstrated benefit to employers as well as employees, the challenge continues in that more employers need to implement such policies in order to change the work–family culture in the United States. When employers strive for goals that benefit both employers and employees, policies will be more progressive than what is required by the government. Improving workplace policies is an ongoing process. Recently, some states have enacted laws requiring employers to offer a limited number of hours annually for parents to attend school-related activities for their children (e.g., California requires 40 hours; District of Columbia requires 24 hours). This indicates employers are beginning to recognize that work–life balance includes everyday life events, such as children's school events, and not just one-time events, such as the birth of a child.

Future Implications

There has been increasing research on the relationship between work and family, but there have not been corresponding advancements in reducing challenges of the work–family interface. Part of the barrier is making clear conceptual definitions including indicators that can be measured. Evidence-based solutions can help on all levels of Bronfenbrenner's bioecological model to create balance in work and family life, but strong research is important to determine their effectiveness. On a macrosystem level, many U.S. companies focus on profits. They are reluctant to help navigate the home lives of their employees as they disregard evidence that exists about higher productivity of employees who feel valued. For individual companies, it is easier to quantify the bottom line than employee satisfaction. Pro-work–family government policies and progressive

companies are in a position of power to influence changes that can achieve productivity and create space for employees to thrive in both work and family domains.

WORK SAMPLING SYSTEM, THE

Finding assessment tools that are developmentally appropriate for young children continues to be a significant challenge in early childhood education. Young children express and represent their thinking in diverse ways: dramatizing, drawing, painting, singing, scribbling and writing, and having conversations. They show what they know and can do with familiar tasks and people they know. The Work Sampling System (WSS) is a research-based, authentic assessment for children from preschool to Grade 3. This performance assessment system, and other early childhood performance assessments, allows teachers to observe and document children's learning as they engage in familiar classroom activities such as drawing, writing, reading, building, and conducting experiments and with familiar adults. This entry presents an overview of the WSS, information about its development, research findings, and a description of how teachers use the WSS.

Overview

The WSS gives teachers a comprehensive means of monitoring students' social, emotional, physical, and academic progress. The assessment is embedded in the curriculum but can be used with any curriculum. The WSS gives teachers clear criteria for evaluation and provides teachers and administrators with tools for summarizing, aggregating, and reporting data so that the assessment information can be used in a variety of ways for decision making.

The Work Sampling System: A Performance Assessment

WSS was developed at the University of Michigan by Samuel J. Meisels and his colleagues (Judy Jablon, Dorothea Marsden, Margo Dichtelmiller, and Aviva Dorfman) in the late 1980s. Originally conceptualized as an alternative to norm-referenced, standardized achievement testing for young children, WSS, a performance assessment, is designed to

show children's achievement by capturing demonstrations of knowledge and skills in classroom settings. Teachers document children's learning and behavior during ongoing classroom activities via observing, collecting work samples, and using rating checklists. In contrast with standardized testing programs, teachers assess young children in developmentally appropriate ways where children perform typical activities in comfortable settings with familiar people.

Development of the WSS began with defining learning expectations based on child development research, state standards, and information from national curriculum organizations. These expectations became the Work Sampling System Guidelines; children's performances were compared with these expectations, making the WSS a criterion-referenced assessment. A version has been customized for Head Start programs and the WSS has an online version.

The initial editions of the WSS focused on summative assessment: assessment that evaluates what children have learned at the end of a period of instruction. Teachers completed WSS checklists and portfolios three times per year and summarized their findings in the Summary Report, a document that replaced a traditional report card. These reports, designed to share with families, eliminated traditional grades, summarized a child's performance and progress, and gave teachers opportunities to write narrative comments about each student.

Over time, as the authors and staff developers collaborated with teachers, they began to see the WSS as an ongoing formative assessment that provided teachers with information to adjust their instruction and students with information about their learning. Unlike summative assessment, the use of formative assessment, especially giving accurate feedback to students about their learning, has shown positive correlations with gains in achievement. The WSS encourages opportunities for student-teacher interactions focusing on assessment and learning.

Research

A significant amount of research has been conducted on the WSS, by its authors, and by independent

researchers. Researchers investigated the validity of the system, teachers' ability to make accurate unbiased ratings, and family perceptions of the benefits of the assessment, among other topics. An early study of a pilot version of the WSS for kindergarten showed that the WSS predicted performance on the Woodcock Johnson-Revised, with correlations ranging from .67 to .76, even when factors such as gender, age, and initial ability were controlled. A cross-sectional study of 17 Title 1 classrooms, conducted in the Pittsburgh Public Schools, demonstrated that WSS ratings in literacy and mathematical thinking were moderately to highly correlated with results on standardized tests. In fact, the WSS was a stronger predictor of test scores than demographic variables. In addition, when students in WSS classrooms were compared with students in classrooms not using WSS, findings indicated that students in WSS classrooms showed more growth in reading than students in non-WSS classrooms, and more than the average growth shown by all other students in the district. These results indicate that the WSS is a valid means of evaluating student achievement and may positively impact achievement levels.

An independent researcher conducted a study of 1,281 students, the majority receiving free or reduced-price school lunches. WSS ratings of literacy and mathematical thinking in first grade predicted third-grade scores on a criterion-referenced, state-mandated test of math and literacy. Results indicated positive, moderately strong relationships across the 2 years for both subject areas. Again, even when demographic variables were controlled, WSS scores predicted later achievement. Finally, a study of a modified version of the WSS used in Minnesota with preschoolers indicated that WSS ratings on the Minnesota version predicted students' scores on the third-grade Minnesota Comprehensive Assessment in reading and math.

Several studies examined teachers' reactions to using the WSS and whether teachers make accurate unbiased ratings. Teachers reported high levels of understanding and implementation of the WSS. Other studies of first-grade teachers using the WSS found that teachers scored African American students lower than White students. However, ethnicity explained only a small amount of the variance in teachers' ratings.

Although only studied in one investigation, families reported that they were very satisfied with the WSS, and approximately two thirds preferred the Work Sampling Summary Report to receiving a traditional report card. Furthermore, parents stated that the WSS helped them understand their child's learning and that it helped children understand their own learning.

Because the fifth edition of the WSS has been recently published, research is just beginning. However, the process that guided this revision was careful and systematic. It involved four processes: (1) an alignment of the fourth edition performance indicators with current state standards and the Common Core State Standards for literacy and math to identify gaps in content; (2) an investigation of the difficulty of the fourth edition performance indicators; (3) review by a panel of early childhood curriculum experts to identify outdated and/or missing content; and (4) focus groups and surveys of current users to identify strengths and weaknesses of the WSS, and suggest revisions. Draft versions of revised materials were reviewed by current users and content experts.

The Work Sampling System 5th Edition

The Work Sampling System 5th edition is composed of two basic elements:

1. Guidelines and checklist. The guidelines describe expectations for children's learning at each grade level. The checklist is a tool to help teachers organize and record evaluative ratings of children's performance on an ongoing basis.
2. Summary reports. Three times each year, teachers summarize and evaluate children's performance and progress using the WSS version of a report card.

Together these elements of the WSS provide teachers with a comprehensive way of documenting and evaluating children's skills, knowledge, and behaviors in seven domains. A domain is a broad area of development. The domains addressed by the WSS are the following:

- Personal and Social Development
- Language and Literacy
- Mathematical Thinking
- Scientific Thinking
- Social Studies
- The Arts
- Physical Development, Health and Safety

Each domain is divided into subsections called components. The components are composed of a set of performance indicators. The domains and components of the WSS are intentionally consistent from age 3 to Grade 3 to foster dialogue among teachers about children's development and learning. To highlight the continuum of development, the Omnibus Guidelines show six levels of development in a two-page spread format. The performance indicators state the skills, behaviors, and accomplishments that are assessed in the classroom. Performance indicators define end of year expectations for each grade level by offering an explanation and examples in the guidelines. To illustrate the relationship of domain, components, and performance indicators, here is an example from one domain at the first-grade level:

Domain: Personal and Social Development

Components

- Self Concept
- Self Control
- Approaches to Learning
- Interaction with Others

Within the component of Self Concept, there are two performance indicators:

1. Demonstrates self-confidence
2. Shows initiative and self-direction

The Work Sampling System 5th edition is organized so that teachers can use the assessment cycle to guide them in the assessment process. Assessment is a cycle with four repeating steps, which are illustrated here with a scenario involving a story-telling lesson in kindergarten. The first step of

the cycle is to *ask questions*. When using the WSS, the performance indicators assist teachers in defining the questions to ask about children's learning. In planning a story retelling experience, Ms. Fox, a kindergarten teacher, looks at the domain of language and literacy, refers to the component of reading, and uses the performance indicators to shape the questions that guide her planning and observing during the lesson.

The second step of the assessment cycle is to *collect evidence*. As teachers interact with children individually and in small groups, they observe and document children's learning in order to collect evidence that answers their questions. During the story-retelling lesson, Ms. Fox observes to see what children understand about the structure of text and whether they can recount key ideas and details from the story. Based on what she notices as she watches and listens to children during the lesson, she begins to use the third step of the assessment cycle, *interpret evidence*. Ms. Fox sees that 5-year-old Leona independently folds her paper into three columns. Ms. Fox begins to interpret her observation or make meaning of it using what she knows from the WSS. She asks herself, "Is this an indication that Leona understands the structure of text—beginning, middle, and end?" Interpreting the evidence in this way leads Ms. Fox to the fourth step of the assessment cycle, *taking action*. Ms. Fox says: "Leona, I see you dividing your paper into three columns. I'm wondering what you are going to do next." Leona responds, "I'm going to draw what happened in the beginning here (pointing to the first column), then the middle and the end."

In this example, Ms. Fox uses the assessment cycle and the WSS as formative assessment—assessment for learning. Her knowledge of the WSS guides her questions and how she responds to children in ways that foster their critical thinking skills. Based on what she learns about children as she interacts with them, she can scaffold their learning in individualized ways.

Following the lesson, Ms. Fox reflects on Leona's work sample and the notes she has jotted and goes deeper with steps 3 and 4 of the assessment cycle. She interprets the evidence further and sees that the documentation she has collected during the lesson

not only tells her about what children know about story retelling but about performance indicators in several domains. As Ms. Fox studies Leona's work and that of other children, she takes action by planning subsequent lessons.

As illustrated in this scenario, using assessment, particularly the WSS, during teacher-child interactions allows teachers to learn about children and simultaneously provide individualized feedback and instruction. Teachers can share their observations with children and ask children about their learning. Children receive immediate and specific feedback based on evidence the teacher documented. Studying work samples enabled interactions focused on learning and next steps.

WORKFORCE DEVELOPMENT

In the field of early childhood education (ECE), there are many employment possibilities. An individual might work directly with children in a classroom or as an administrator. Many of the positions in the classroom have titles that are used interchangeably depending on the region, program, or preference of the individual. For example, sometimes the term *teacher* is used to refer to the person who is responsible for classroom activities and routines while other times the term *care-giver* is used. Administrators could include midlevel managers, senior management, curriculum specialists, and training specialists. Because there are a variety of positions that could be held, when early childhood professionals talk about the professional development of workers at all levels they use the terminology *workforce development*.

Types of Professional Development

There are many ways individuals can prepare to work in the field of ECE. As will be discussed next, qualifications range based on location and type of program. Although some programs do not require much preparation to work with young children, research demonstrates that the experiences and outcomes for children are better when their teachers and administrators have more education related to their work with young children.

Formal Models of Training and Development

A Child Development Associate (CDA) credential is an endorsement by the national Council for Professional Recognition. A practitioner may apply for and receive this recognition after he or she completes 120 hours of training, completes 480 hours of professional experience with a targeted age group

of children, submits written evidence of his or her knowledge and skills, and passes an exam. The credential is valid for 3 years and then must be renewed. A CDA can be earned focusing on working with infants and toddlers, preschoolers, as a family child care provider, or to be a home visitor.

Some individuals who want to work with young children take college classes and earn a degree related to ECE. There are two general college pathways that prepare the workforce. Practitioners can take courses in a health and human development program (sometimes called health and family studies or child development and family studies) or courses in a teacher education preparation program. Choosing between the two program types depends on a person's long-term career goal as well as institutional differences in offerings. Typically, teacher education programs lead to state licensing certification, a requirement for some early childhood positions. However, variations at colleges or universities exist so that early childhood certification may be offered through a department such as human development and family studies. Both pathways require a minimum number of credit hours, successful completion of required courses and electives, and approved experiences working with children.

Traditional Models of Development

Another avenue for preparing and staying current with best practices in the field is through workshops and conferences. These can be face to face, online, or a hybrid of both. Stand-alone workshops are offered on specific topics. A series of workshops may be provided that build knowledge and skills over time. Sometimes a child care program will invite a qualified trainer to come to the program site and train all the staff together or at other times training is offered at a central location and specific staff are targeted to attend based on their position or need for further development. Conferences are generally an array of workshops offered on the same day or over several days that span a variety of topics. They are offered nationally or through a local or state early childhood agency or association.

Modern Models of Development

Many agencies promote and offer professional development through more individualized and personal methods. Coaching, mentoring, and reflective supervision are a few of the commonly used strategies. These methods allow a facilitator to work one-on-one or with a small group of practitioners to develop knowledge and skills. Advantages of these forms of development are the ability to customize content to the learners' needs, give specific feedback, and to work together over a span of time.

Qualifications

In the United States, minimum qualifications for all licensed positions vary by state. According to Child Care Aware of America's website, some states allow lead teachers to have less than a high school diploma or GED certificate while others require college degrees. Similarly, requirements to be a director of a child care center vary from state to state. Some states allow directors to have less than a high school diploma while some require college credits in ECE or a college degree.

Head Start, a federally funded and monitored program, has higher expectations for staff qualifications. They require that within a classroom, teachers have at minimum an associate's degree in ECE or a related field. In addition, nationally a minimum of half of all teachers in Head Start programs must have at least a bachelor's degree in ECE (or an advanced degree with courses equivalent to an ECE degree) and professional experience working with young children.

The National Association for the Education of Young Children (NAEYC) accredits high-quality programs. Programs can apply for accreditation after completing a self-study of their practices, policies, and procedures. One standard required for national accreditation by NAEYC relates to staff qualifications. To meet NAEYC qualifications, a lead teacher can have a CDA but must be working on a college degree. An administrator must have at least a bachelor's degree and targeted college coursework. When administrators do not meet those qualifications, they will submit a plan for achieving that

goal in 5 years or, alternatively, evidence that guidelines have been met through another pathway.

Many states are implementing quality rating and improvement systems (QRISs) that are designed to raise the quality of child care programs. QRISs typically include minimal staff qualifications for each tier of the system. For programs to advance to the next tier, staff qualifications must increase for both teachers and administrators.

assistance, and policy advice to developing countries (i.e., low-income and middle-income countries). The name actually refers to two organizations that share leadership and staff: the International Bank for Reconstruction and Development (IBRD) and its concessional lending arm, the International Monetary Fund (IMF). Led by the United States and United Kingdom, a multinational group of governments created the World Bank in 1944 to create an economic architecture to help reconstruct and develop European countries devastated by World War II. Its goal quickly expanded to providing support to non-European countries, and its current goal is to eradicate poverty worldwide. It is one of five international organizations in the World Bank Group, is a member of the United Nations Development Group, and includes 188 member countries. It is considered a premier international development institution because of both its financial and intellectual prowess.

Education as a Poverty Reduction Strategy

The World Bank has multiple strategies to reduce poverty, such as improving a country's infrastructure, social services, or capacity in specific sectors such as agriculture or health. One of its major strategies to reduce the effects and rates of poverty is education. Its focus on education has increased in the 2010s, with financial support rising from \$1.8 billion in 2011 to \$2.9 billion in 2013, and technical assistance following suit. Notable education projects and partnerships include the Russia Education Aid for Development (READ) Trust Fund program, the Results in Education for All Children (REACH) program, and the Global Partnership for Education, for example. World Bank projects and assistance have led to positive impacts in the education domain, including reduced numbers of out-of-school children (from 105 million children of primary school age out of school in 1990 to 57 million in 2011), increased primary school completion rates (from 81% in 1991 to 91% in 2011), and increased enrollment rates in preprimary school.

WORLD BANK

The World Bank is an international financial institution that provides loans and grants, technical

Early Childhood Development as a Key, Multisectoral Investment

World Bank leaders are acutely aware of the unique challenges and pernicious ramifications of weak early childhood development (ECD) systems and the clear evidence of the benefits of investments in ECD. As such, ECD plays a critical role in the World Bank's overall education strategy. In 2011, the World Bank launched its Education Sector Strategy 2020, which sets the goal of achieving learning for all, and includes a distinct emphasis on early childhood development. The three pillars of the strategy are "Invest early. Invest smartly. Invest for all."

However, education is only one sector in which ECD plays a key role. It also features heavily in health, social protection, and other sectors. Scaling Up Nutrition (SUN), for example, has been a major health initiative focusing on children's first 1,000 days. In other words, the World Bank uses many entry points to impact ECD and improve outcomes for young children, including health care, hygiene, nutrition, parenting programs, child protection programs, conditional cash transfer programs, and early childhood education programs.

The World Bank is increasingly supporting ECD investments globally by financing programs, providing policy advice and technical support, and partnering with other stakeholders at country, regional, and global levels. The World Bank invested more than \$3.3 billion between 2001 and 2013.

ECD Program Implementation and Results

As a result of these efforts, effects are evident in countries around the world. In Haiti, for example, about 1.8 million families have access from 2013 to 2019 to maternal and child health, nutrition, and social services. In Vietnam, in a 2013–2017 program, disadvantaged 3- to 5-year-olds benefit from a school readiness program. In Mozambique, a 2012–2017 program will reach 84,000 children in 600 rural areas to improve early skills in cognitive, linguistic, social-emotional, and physical skills. Some projects have extensive reach

throughout an entire region, such as the Early Childhood Initiative: An Investment for Life that operates throughout Latin America, or the Early Learning Partnership program that targets assistance to sub-Saharan Africa. Overall, the World Bank implemented 273 ECD activities from 2001 to 2013.

SABER-ECD

The World Bank has long valued the importance of good measures, rigorous data collection, and evidence-based decision making to ensure results and accountability. Recognizing the particular challenges to policy makers in creating a strong early ECD system, given its multisectoral nature and the importance of coordinating with many stakeholders, the World Bank has created a new measure to improve countries' abilities to understand and improve their ECD systems. The Systems Approach for Better Education Results (SABER)-ECD collects, synthesizes, and disseminates comprehensive information on ECD policies and programs across different systems. Each participating country collects data to assess its progress toward three ECD policy goals:

1. Establishing an enabling environment;
2. Implementing widely; and
3. Monitoring and ensuring quality.

To do this, governments take stock of the programs already operating in their country, analyze information to evaluate the level of development of ECD policies, and identify options for strengthening their ECD policies, based on international comparisons. The World Bank does not rank countries based on their results but rather provides detailed guidance that the country can use to improve their system. As of early 2015, 15 countries had participated in the SABER-ECD process.

Partnerships, Competitors, and Critics

In addition to partnering with governments, the World Bank works in alliance with many organizations at many levels to impact education and

early childhood development in particular, including UNICEF, UNESCO, the World Health Organization, bilateral donor agencies, foundations, international nongovernmental organizations, and special groups such as the Consultative Group on Early Childhood Care and Development. Other international development agencies also aim to influence the global ECD agenda and compete for donor dollars, such as the Asian Development Bank, Inter-American Development Bank, and most recently, the Asian Infrastructure Investment Bank. Critics of the World Bank say it is a large bureaucracy and staff is too often appointed on the political whims of member states. They also suggest that current education strategies may connect too closely with the private sector, diminishing the responsibility of the state, and do not sufficiently account for how the various dimensions of poverty interface with learning conditions and local norms. Regardless, the World Bank is a critical player on the global stage in impacting ECD policies, investing in programs, and increasing demand for and capacity in developing countries to improve ECD services.

ZERO TO THREE

ZERO TO THREE is a national, nonprofit organization that focuses on promoting the well-being of children birth to 3 years of age. The mission of ZERO TO THREE “is to ensure that all babies and toddlers have a strong start in life” (ZERO TO THREE, n.d.).

History, Resources, and Services

The ZERO TO THREE organization was established in 1977 by a multidisciplinary group of mental health, child development, and health experts who were interested in addressing and intervening in issues impacting the optimal development of young children. ZERO TO THREE has now expanded into a comprehensive organization that plays major leadership roles in identifying and addressing key issues that impact the well-being of young children and their families. The organization has two office locations, an eastern office located in Washington, D.C., and a western office located in Los Angeles, California.

The information and services provided by ZERO TO THREE are multidisciplinary, collaborative, culturally responsive, and clinically informed. These resources and services are designed to promote an understanding of key societal, developmental, and

family issues that impact optimal outcomes for infants and toddlers. The multidisciplinary approach of the organization brings together the research perspectives of specialists from many professional fields. The specific type of research most relevant to the work of ZERO TO THREE are those studies that focus on the interrelatedness of all domains of child development (social, emotional, intellectual, language and physical) and the importance and impact of family on every child’s development.

ZERO TO THREE helps parents and professionals get information on education and intervention services for children and families that promote children’s overall growth, development, health, and well-being within the context of family and culture. The organization does not charge a fee for membership. Individuals, families, and professionals may join ZERO TO THREE through the organization’s website. The organization offers a variety of resources, including the following:

Fellowships

The Leaders for the 21st Century fellowship program offered by ZERO TO THREE is a national program that brings together professionals from a range of disciplines. The purpose of the fellowship program is to expand the participants’ scientific knowledge of early childhood and to provide leadership training.

Publications

ZERO TO THREE offers publications on research, practical resources, brochures, and other materials for individuals who work with infants, toddlers, and families. The publications address a variety of topics including normative and atypical child development, early care and education, early intervention, early literacy, infant mental health and trauma, parenting, and policy issues. Publications are also available in Spanish. In addition there are training resources and materials available.

ZERO TO THREE publishes a bimonthly (six issues per year) journal designed for use by early childhood experts, early interventionists, and child care professionals. The journal features evidence-based practices that impact the health and well-being of young children. It specifically focuses on topics that are relevant to professionals who work with children from birth to 3 years old and their families. A subscription fee is charged and a print or digital form of the *Zero to Three* journal is available. For an additional fee, professionals can earn continuing education units with each issue of the journal.

Training and Professional Development

The organization provides evidence-based informed training for professionals who work with infants, toddlers, and families. Professional development for trainers and practitioners working in early care and education, early childhood mental health, child welfare, and early childhood intervention are available.

Electronic Resources

The ZERO TO THREE website provides an extensive amount of information and resources designed for use by professionals, families, policy makers, and others. Most of these resources are provided at no charge and are available in multiple formats. Users of the website can sign up to receive a monthly newsletter and e-mails on specific topics and join the organization's policy network. The ZERO TO THREE Web-based information,

materials, and resources are designed around several broad topics relevant to infants, toddlers, families, and public policies. As of early 2015, the following topics and information were available on the ZERO TO THREE website:

Public Policy

The public policy section of the website provides information for policy makers on the developmental needs of infants and toddlers. It includes tools for effective advocacy and resources on building comprehensive early childhood systems, federal policy, infant-toddler policy issues, and state and community policy.

Behavior and Development

In this section of the website are resources focused on the behavior and development of infants and toddlers. It includes the following:

Little Kids, Big Questions. This is a series of 12 podcasts on early childhood development. The series focuses on common challenges and issues that parents of babies and toddlers may experience, such as crying and sleep. Each podcast features an expert who is interviewed about how research can be applied in daily interactions with a young child.

Brain Development. This section provides information on brain development during the first 3 years of life. In addition it offers information on how parents, caregivers, and others can help young children get a good start in life, which leads to lifelong learning.

Challenging Behaviors. The resources in this section focus on how to help parents understand and respond to challenging behaviors that young children may exhibit. Examples of some of the behaviors addressed are crying, aggressive behavior, and sleep.

Early Childhood Mental Health. This section includes resources focused on understanding infant and early childhood mental health and how to identify and treat mental health concerns.

Early Development. Information and resources about early development and what parents and others can do to support young children's development can be found here.

Health and Nutrition. Resources on a range of health issues are presented to help parents and others nurture young children's growth and development.

Mental Health Screening and Assessment. This section contains information for early childhood practitioners and parents who may be concerned about a child's development and also strategies they can jointly use to determine if a child has a developmental delay.

Play. How and why play is important for young children's development is the focus of this section.

Promoting Social Emotional Development. This section focuses on how social and emotional development occurs and how adults can support young children's healthy social and emotional development.

Sleep. This section provides information and strategies designed to help young children sleep.

Temperament and Behavior. Information and resources in this section focus on children's temperament characteristics and how these characteristics are vital to understanding children's behavior and the way they respond and interact with the environment and other people.

Maltreatment

This section includes resources on the impact of child maltreatment and sources of trauma such as exposure to violence, loss, or disaster. Resources for how to respond to the needs of young children and their families who have experienced trauma are provided. The topics in this section include child abuse and neglect, the impact of trauma, and Safe Babies Court Teams, a project to increase awareness about the negative impact of abuse and neglect on young children and to prevent court involvement in the lives of young children.

Early Care and Education

This section focuses on the need for high-quality, positive early learning experiences for babies and toddlers in child care. It includes information on how to identify high-quality child care for infants and toddlers; information on caring for the children of family, friends, and neighbors; and an interactive learning activity designed to help parents and caregivers support their young children's early learning.

Military Family Projects

At the bottom of the ZERO TO THREE home page is a link to a discussion of the organization's Military Family Projects. These projects are designed to support military and veteran families and their children. The goal of these projects is to increase awareness and collaboration in military and civilian communities so that professionals who work with parents and children can more effectively care for children birth to 3 years old in military-connected families. ZERO TO THREE resources available on this topic include board books for toddlers, booklets for parents, and strategy guides for professional who work with military-connected families designed to strengthen and provide a good foundation at the beginning of a child's life as well as to help build young children's resilience.

National Training Institute

ZERO TO THREE holds an annual National Training Institute designed to provide professional development opportunities for those working in early childhood education, Early Head Start, early intervention, parent education, pediatrics, and mental health. A link to information on the yearly ZERO TO THREE National Training Institute can be found at the bottom of the ZERO TO THREE home page.

Early Head Start National Resource Center

A link to the Early Head Start National Resource Center can be found at the bottom of the ZERO TO THREE home page.

Maternal, Infant, and Early Childhood Home Visiting Technical Assistance Coordinating Center (MIECHV TACC)

ZERO TO THREE is a partner in the MIECHV TACC and a link to the center can be found at the bottom of the ZERO TO THREE website home page. MIECHV TACC provides technical assistance to support programs funded through federal grants to provide home visiting services.

Free Parenting App

In addition to the resources available on its website, ZERO TO THREE offers a free parenting application titled LET'S PLAY! The app provides activities that parents can do with young children. These activities are presented by age and are designed to enhance and support young children's early learning. The application is available for download from Google Play Store and iTunes.

Conclusion

For those who work with young children and families, ZERO TO THREE is a valuable source

for current, research-based information. It also provides leadership and advocacy on behalf of young children and identifies and addresses key issues that impact the well-being of young children and their families. The organization's multidisciplinary approach brings together a wide range of research perspectives from a variety of professional specialists. ZERO TO THREE emphasizes the importance of education and intervention services for children and families and the need for professionals to work together in efforts to promote young children's overall growth, development, health, and well-being.

Appendix

Resource Guide

The following agencies, professional associations, and websites are of particular relevance to the field of early childhood education.

Association for Childhood Education International (ACEI). <https://acei.org>

ACEI is an international advocacy community with a focus on promoting both quality education and positive childhood experiences for all children around the world. Membership is made up of educators and other advocates who base their perspective on current knowledge and experience in order to share information and innovation related to education for all learners, birth through adolescence. First established as the International Kindergarten Union (IKU) in 1892, it changed its name in 1946 to the Association for Childhood Education International. ACEI has a history of work related to early childhood education. The association's publications are highly regarded and include *Childhood Education*, *Journal of Research in Childhood Education*, and *Early Years Bulletin*.

Association for Supervision and Curriculum Development (ASCD). www.ascd.org

ASCD focuses on improving learning experiences for children of all ages. Since 1943, this association has engaged in advocacy and other initiatives that promote the success of each learner. An initiative that has been particularly supportive of early childhood education is known as “the

whole child.” This project is based on five tenets: (1) the importance of child health, (2) safe environments for learning, (3) active engagement and connection with school and community, (4) children’s need for supportive adults, and (5) providing appropriate academic challenges to prepare learners to participate in a global environment. The ASCD website provides detailed information about these tenets as well as an assessment tool for educational leaders to measure their efforts regarding the whole child.

Center on the Developing Child at Harvard University. www.developingchild.harvard.edu

The Center on the Developing Child at Harvard University, led by professor of pediatrics Jack Shonkoff, has focused on creating a global research and development platform with the intent of achieving optimal life outcomes for children who face adversity. The center’s work involves three functions: conducting science and translating results for nonscientists to apply in their work; designing, testing, and refining intervention strategies through both pilot projects and large-scale projects; and supporting a learning community to adopt promising projects. Results from several areas that are referred to as “deep dives” have been translated for nonscientists: lifelong health, gene-environment interaction, neglect, and early childhood mental health. With an emphasis on knowledge gained from neuroscience, reports and multimedia presentations yield

explanations for early childhood practitioners about the negative effects of neglect and trauma. On the other hand, children develop executive function and self-regulation skills for relating to their environments when they receive necessary support from families and early childhood education programs. Adults who create reliable routines for children, model prosocial behavior, and engage with children in authentic ways to create positive relationships help to foster these necessary skills.

In addition, children need opportunities for selecting and engaging in a variety of child-directed play activities, plenty of exercise, and opportunities to learn about appropriate ways to cope with stress. In short, neuroscience helps early childhood educators and families to understand that social and emotional factors, along with cognitive and academic achievements, are necessary for children's lifelong success. As increasing knowledge is gained about brain development, one of the most important concepts for understanding the importance of early childhood education is that strong brain circuits are more easily formed in the early years than engaging in interventions to modify these circuits later on.

Center on the Social and Emotional Foundations for Early Learning (CSEFEL).
<http://csefel.vanderbilt.edu>

CSEFEL is a national resource center for promoting social and emotional development to support academic success in young children from birth through 5 years of age. The center is funded by the Office of Head Start and the Child Care Bureau, and has as its mission the dissemination of evidence-based educational practices in early childhood programs. The CSEFEL website contains a treasure trove of professional development materials for implementing the pyramid model. This model has been put into practice by many early childhood educators and is known to support social and emotional competence in children from birth through 5 years. The pyramid model demonstrates that at the foundation, or base, all children need and benefit from a highly skilled

early childhood education workforce with policies in place for the application of evidence-based practices that support young children's social and emotional development.

As the title of the center indicates, the social and emotional realms are requisite for optimal early learning. The pyramid model offers additional components indicating that all children benefit from nurturing and responsive relationships in supportive learning environments with early childhood professionals. As the pyramid closes in near the apex, a component demonstrates that some children will need "targeted social and emotional supports" in order to prevent challenging behaviors or explicitly remind children about expected behavior. Finally, a few children are likely to need more intensive intervention that is designed specifically for them and based on reliable assessments. The importance of the pyramid model to early education is the designation about what all children need from high-quality early educational experiences and also that some children will need well-designed appropriate supports to maximize their potential. Examples of supports include scripted stories about various social situations, effective strategies for encouraging children with positive feedback, and explicit teaching of social and emotional skills with examples such as posters showing steps for solving problems or identification of emotions through pictures of faces that demonstrate feelings.

The CSEFEL website includes professional development modules for early childhood teachers and parents working with infants and toddlers or preschoolers. Videos that demonstrate strategies for fostering social and emotional competence, collaboration, and the pyramid model are available on the website. In addition, a series of *What Works Briefs*, available in both English and Spanish, address topics such as classroom routines and schedules, helping children to transition from one activity to another, supporting peer relationships, and what children are trying to communicate through their behavior.

Child Care Aware. www.usa.childcareaware.org

Child Care Aware is an organization that provides resources and tools for both child care providers and families, and has a primary focus of increasing the quality of the child care system. For prospective child care providers, it provides information about how to get started; writing business, management, and program plans; and information about required training. For families, the website provides details about types of child care and how to recognize quality care, along with access to an online newsletter. Members include resource and referral agencies, state network organizations, nonprofits and government agencies, as well as interested individuals such as child care providers, early childhood education students, and child and family advocates. On the website, readers will find details about implementing the Child Care and Development Block Grant (CCDBG) laws for each state and related webinars. The Family Network of Child Care Aware acts as a community of various family member advocates who are committed to increasing quality of child care programs for all children. Information is also provided about military child care programs and ways that military families may be able to get assistance to pay for child care.

**Child Care Exchange.
<https://childcareexchange.com>**

Child Care Exchange is an organization that has been providing support for professional development for early childhood educators to create positive environments for young children to thrive around the world. Founded by Roger and Bonnie Neugebauer in Redmond, Washington, its excellent magazine, *Child Care Information Exchange*, was first published in 1978 and continues to provide essential information about child development, safe and healthy environments, leadership, and staff development to child care center administrators. Other noteworthy initiatives of Child Care Exchange include the World Forum, training kits, and books. Since 1999, the World Forum has offered a unique opportunity for early education

leaders to participate in a global exchange of ideas about quality educational services for young children in a multitude of settings. Successful Forum events have been held in Honolulu, Singapore, Athens, Acapulco, Kuala Lumpur, Budapest, and San Juan, among other cities. Training kits for staff development are offered at reasonable prices and are based on current research and best practice on categories including administration, child development, curriculum, environments, family, and leadership. Each kit is based on an article from *Child Care Information Exchange* and includes suggestions for conducting and evaluating professional development sessions.

**Child Welfare League of America (CWLA).
www.cwla.org**

The CWLA is a coalition of agencies with a goal of assisting vulnerable children and families. Since 1920, the Child Welfare League of America has served as a collaborative to advance policies and practices that lead to optimal outcomes for children who may have experienced trauma such as abuse or family disruption, as well as support for adult caregivers of traumatized children. The vision that all children will have an opportunity to grow and develop within loving families and supportive communities holds a perspective that is essential to successful early childhood education. At its website, CWLA provides detailed information about both its advocacy and practice initiatives that include the essentials of high-quality care for all children.

**Children's Defense Fund (CDF).
www.childrensdefense.org**

Marian Wright Edelman, the first Black woman licensed by the Mississippi bar, founded the Children's Defense Fund in 1973 as part of her civil rights work. Over four decades, the Children's Defense Fund has served as a faith-based and unyielding advocate for improving policies and programs for all children in the United States. Attention has been given to policy needs of children and families in poverty so that all may fulfill their optimal potential. Current

policy priorities of CDF include ending child poverty; ensuring that all children have access to affordable medical care; guaranteeing that all vulnerable children have access to high-quality early childhood education such as Early Head Start, Head Start, child care, preschool, and full-day kindergarten; ensuring that elementary and secondary education serve as equalizers by riding school policies of plans that reinforce barriers created by poverty and racism; engaging in child welfare reform movements so that all children have a safe start in a permanent nurturing family; and building awareness of unfair practices in juvenile justice that have led to a cradle-to-prison system. Although the policy priorities for early childhood education and elementary and secondary education most closely relate to best practices and positive educational outcomes for young children, the comprehensive view taken by CDF supports children's needs for family, health, community, and safety—all essential for successful early education.

One CDF initiative that addresses all policy priorities is Freedom Schools, a summer and after-school literacy enrichment project for children who might not have access to books. Freedom Schools curriculum has been an important factor in helping to limit learning loss that occurs over the summer as well as in closing achievement gaps. Five components of the Freedom Schools program are high-quality learning experiences, family engagement, social action, intergenerational practices, and nutrition and health for wellness.

Children Now. www.childrennow.org

Children Now is an advocacy organization with a mission of improving the lives of children. Information on the website compares Children Now to the American Association of Retired Persons (AARP) for older adults and Chambers of Commerce for business. Three issue categories that this organization has adopted are education, health, and child welfare. Education topics that relate to early childhood include infant and toddler care, preschool investments, kindergarten

readiness, and school climate. Health topics that are addressed by Children Now and related to early childhood include health care access, home visiting, developmental and behavioral screening exams, oral health, mental health, and childhood trauma. This organization also participates in advocacy efforts to ensure that foster children receive targeted education supports and services, and points out the critical nature of stability for children.

Community Advocates for Young Learners (CAYL) Institute. www.cayl.org

The CAYL Institute, founded in 2004, has as its mission the organization, equipping, and empowering of people to create change on behalf of children. A child's right to high-quality early care and education in the United States is embedded in policy, professional practice, and parental engagement. A major offering from the Massachusetts-based organization is professional development for educators and community leaders. CAYL Institute leaders focus on sharing new ways of thinking about the needs of young learners, programs for young learners, and community involvement. A variety of policy papers are available on the CAYL Institute website, including topics such as coordinated social-emotional supports, early education and care workforce development, helping elementary school principals learn about pre-K practices, ensuring high quality, and cultural competence.

Consumer Product Safety Commission (CPSC). www.cpsc.gov

The Consumer Product Safety Commission is a United States government agency with the mission of identifying hazards and monitoring, regulating, and enforcing safety concerns. Safety education centers on the website include cribs, window covering cords, poison prevention, magnets, and pool safety. Each one of the safety centers provides details and videos about the topic. The Office of Legislative Affairs serves as an intermediary between CPSC and Congressional committees by assisting in regard to commission

policy and coordinating testimony as needed to Congress. CPSC is related to early childhood education through its attention to toy safety. In addition to regulating toy safety, CPSC provides information about safe toys by children's age through downloadable consumer guides. One publication offered by the commission, *Think Toy Safety—by Knowing Toy Dangers*, provides lists of details to consider when buying, maintaining, sorting, and storing toys for young children. Information that is especially useful to early childhood education programs deals with furnishings and playground equipment and safety.

Council for Exceptional Children (CEC).
<https://www.cec.sped.org>

The Council for Exceptional Children is a professional association that provides members with information about working with and advocating for children with exceptionalities, both special needs and giftedness. CEC leadership has created position statements and policy briefs on topics such as school vouchers, response to intervention, assessment and accountability, community-based services, and safe and positive school climate. In addition, a series of issue briefs include topics related to early childhood education, such as *Improving Outcomes for Children With Disabilities Through High-Quality Early Learning Programs* and *School Climate and Mental Health*. Among the various special interest divisions for members of CEC is the Division for Early Childhood (DEC), which has a focus on best educational practices for children from birth through 8 years of age who have a disability or other special need.

DEC publishes two journals—*Journal of Early Intervention* and *Young Exceptional Children*—as well as position statements about topics such as challenging behavior, professional ethics, inclusion, and family culture.

Council for Professional Recognition.
www.cdacouncil.org

The Council for Professional Recognition is most well known for administering the Child

Development Associate (CDA) National Credentialing Program. In order to earn a CDA, candidates must complete at least 120 hours of formal education in early childhood by completing at least 10 hours in each of eight content areas: (1) planning safe and healthy learning environments; (2) advancing children's physical and intellectual development; (3) supporting children's social and emotional development; (4) building reciprocal relationships with families; (5) managing effective programs; (6) committing to professional behavior; (7) observing and recording children's behavior; and (8) understanding principles of child development and learning. In addition, candidates must complete at least 480 hours of supervised work experience with young children. To complete the application process, candidates must prepare and submit a professional portfolio of their education and work experiences as well as pass a written exam. The CDA is a highly regarded credential and is a step toward completing a baccalaureate degree for many early childhood educators.

The mission of the Council for Professional Recognition has been to increase performance and recognition of early childhood educators who work with children from birth through age 5 years. The council is led by Chief Executive Officer Valora Washington. Washington has had a distinguished career in early childhood education and has authored many publications related to effective advocacy work.

**Department of Health and Human Services,
 Administration for Children and Families (ACF).**
www.acf.hhs.gov

Within the federal government's Department of Health and Human Services, the Administration for Children and Families exists, as stated on the home page of its website, to "promote the economic and social well-being of families, children, individuals and communities with partnerships, funding, guidance, training and technical assistance." Programs that ACF sponsors for young children and families deal with adoption, child abuse and neglect prevention and intervention,

child care, early childhood development, Head Start, foster care, and child welfare. The Children's Bureau, an office of ACF, works to decrease barriers to adoption and to assist in finding permanent families for children in the adoption system, including those who are in foster care. Initiatives relating to child abuse and neglect are also under the auspices of the Children's Bureau. Funding is provided to states and tribes for family-strengths projects and also for child abuse and neglect prevention and intervention. The Office of Early Childhood Development at ACF includes the Offices of Child Care and Head Start, as well as the Interagency Team with the mission of a federal-level collaboration to improve access to high-quality early childhood education programs. ACF works to create a strong and purposeful early learning and development system with Head Start, child care, and prekindergarten programs. In addition, ACF publishes a monthly newsletter that highlights policies and milestones related to early childhood education.

Environmental Rating Scales Institute (ERSI).
www.ersi.info

Researchers at the Frank Porter Graham Child Development Institute at the University of North Carolina at Chapel Hill created four variations of environmental rating scales as follows: infant and toddler, preschool and kindergarten, family child care, and school age before and after programs for children ages 5 to 12 years. The first scale to be developed was the Early Childhood Environment Rating Scale (ECERS) for use in evaluating preschool programs; a third edition was published in 2014. Thelma Harms, Richard Clifford, and Debby Cryer authored this edition, which is a major revision based on current evidence and is made up of 35 items in six subscales: space and furnishings, personal care routines, language and literacy, learning activities, interactions, and program structure.

The Infant/Toddler Environment Rating Scale, Revised Edition (ITERS-R), authored by Harms, Cryer, and Clifford, is made up of 39 items in seven subscales: space and furnishings, personal

care routines, listening and talking, activities, interaction, program structure, and parents and staff. Made up of 38 items and seven subscales, the Family Child Care Environment Rating Scale, Revised Edition (FCCERS-R) was authored by Harms, Cryer, and Clifford. The subscales of the FCCERS-R are space and furnishings, personal care routines, listening and talking, activities, interactions, program structure, and parents and provider. The School-Age Care Environment Rating Scale, Updated Edition (SACERS-Updated), authored by Harms, Ellen Vineberg Jacobs, and Donna Romano White, contains 49 items in seven subscales: space and furnishings, health and safety, activities, interactions, program structure, staff development, and special needs. The purpose of each scale is to assess quality of classroom processes in various age groups or environments. The Environmental Rating Scales have high reliability and validity, and all data are collected through observation. Observations based on the items in each scale lead to useful program evaluation data. Because of the ease of data collection and content validity, the Environmental Rating Scales are widely used in various quality systems for child care.

Families and Work Institute (FWI).
www.familiesandwork.org

In 1989, Ellen Galinsky and Dana Friedman founded the Families and Work Institute as a non-profit think tank and action tank to study changes in the workforce, families, and communities in three primary categories: the workplace, youth, and early childhood. Some current topics of study are effective workplaces; life skills and executive function; children, youth, and learning; quality of education; community schools; and the low-wage workforce and upward mobility. Attention to the realm of early childhood has led FWI to identify seven evidence-based life skills that every child needs to succeed. The skills are focus and self-control; perspective-taking; communicating; making connections in their worlds; critical thinking; taking on challenges; and self-directed engaged learning. Galinsky has authored a book, *Mind in*

the Making: Seven Essential Life Skills Every Child Needs, which describes each of the necessary life skills as well as ways that families and teachers might best support development of these skills. The FWI website has an extremely useful teaching tool for supporting the life skills: a listing of children's books that are aligned with the appropriate skill and age group, as well as downloadable tip sheets for reading each of the books. *Mind in the Making* has gone beyond the confines of a useful book for parents and teachers of young children to an initiative with national attention. Parent and early childhood teacher education programs are in place as well as a series of lectures and forums. The seven life skills provide an effective basis for curriculum development in early childhood education. A discussion guide can be found on the website that serves as an effective tool for both parents and teachers to better understand meaning and strategies for each of the seven life skills for children.

Harvard Family Research Project (HFRP).
<http://hfrp.org>

Since 1983, the Harvard Family Research Project has provided a national focus on partnership perspectives related to family and community engagement research, practices, and policies. It is the intent of HFRP to increase policy and program support for learning across multiple settings: schools, homes, and communities. Specific to early childhood education, HFRP emphasizes that family and community partnerships need to be built into all school practices in order to best promote children's development and learning. Six areas of practice have been identified as key to influencing positive child outcomes: educational program environment, child transitions, engaging families as teachers, home visiting, educator-family reciprocal relationships, and community partnerships. Staff at HFRP note that these practices will only be effective when necessary foundations are considered; these foundations are professional development regarding family and community engagement, education program leadership that is knowledgeable and supportive of family and

community engagement, and ongoing evaluation that leads to continuous improvement. At the HFRP website, resources are available to provide details about each of the six areas of practice and the three foundational premises. Several one-page digests relate family engagement topics to early education settings with applied information; they include *Helping Parents Communicate Better With Schools* and *Families and Teachers as Partners*.

HFRP supports a community of educators, policy makers, and researchers who are committed to strengthening partnerships among schools, families, and communities. Known as Family Involvement Network of Educators (FINE), members of this collaborative have access to resources and ideas free of charge. All perspectives are based on current research in the areas of family involvement in children's education. Newsletters are published four times a year and web chats are available.

Heckman Equation.
www.heckmanequation.org

The Heckman Equation website contains economic information related to early childhood education. Nobel Prize-winning economics professor James Heckman suggests that investments in early childhood development and education are the basis for the development of human potential. Through the eyes of an outstanding economist, this website indicates the far-reaching impacts for a society that values and provides early educational experiences, especially for at-risk children. Heckman notes that improvements to the economy, reducing the deficit, and strengthening the middle class are national priorities in the United States and that all of these issues can be addressed through high-quality early childhood education programs. According to Heckman, a proactive approach of early childhood education decreases the achievement gap; coordinated and comprehensive birth to 5 years programs have been shown to improve children's health; children who participate in quality early intervention programs earn better wages as adults; and the rate of return for investing in early education is 7% to 10% annually through more positive outcomes

in educational attainment, health, social competence, productivity, and reduction in criminal behavior.

Heckman takes on the myth in regard to fade out of positive outcomes from early childhood education by addressing the limited information given by third-grade test scores. Tests that measure only cognitive gains are skipping over the importance of social and emotional skills necessary for life success. Characteristics such as conscientiousness, motivation, self-control, persistence, and sociability have been shown to be essential for workplace and family success. The Heckman Equation website has provided strong arguments for providing high-quality early childhood education, especially for children of families with risk factors. The economic perspective gives additional weight to the whole child perspective in early childhood education.

Home Instruction for Parents and Preschool Youngsters (HIPPY). www.hippy-international.org

Home Instruction for Parents and Preschool Youngsters is an international venture for parents and their 3- to 5-year-old children that began in Israel and is now present in at least 10 countries, including the United States. Concerned with equal educational opportunity and inclusive practices, HIPPY is especially successful with families and communities who have socioeconomic challenges as it supports parents and other caregivers to foster children's school readiness and motivation. With an ambitious agenda, HIPPY programs intend to nurture parent confidence in teaching their children, build positive parent-child interactions, create interest in and love for books, and assist families to engage in their communities and to gain work experience and skills. As indicated in the title of the program, HIPPY takes the curriculum for young children and their parents into their homes and provides one-on-one support to parents as they create an environment with many rich learning opportunities for their children. Through this approach, parents receive job training and establish goals for additional work-related possibilities. The curriculum focuses on how to prepare

children to have positive school experiences through language development, perceptual and sensory discrimination, logical thinking, and problem solving. Strategies for addressing these outcomes include reading, writing, singing, rhyming, drawing, cooking, and putting together puzzles. Both short- and long-term outcomes have resulted from HIPPY program experiences. Stronger parent-child relationships, children's readiness for school, parent increase in child development knowledge, and creating rich learning environments at home are some of the many short-term outcomes. Long-term outcomes are increased high school graduation rates and breaking away from a cycle of poverty.

International Literacy Association (ILA). <http://literacyworldwide.org>

Since 1955, ILA (formerly the International Reading Association—IRA) has focused on the importance of literacy instruction through research on best instructional practices and professional development for teachers of reading. The change in name came about as leaders and members of the association chose to promote their belief that “literacy is the primary foundation of all learning.” ILA has set 11 assessment and teaching standards for all literacy educators who work with any age group, preschoolers through adults. Among the standards are that student interests are paramount in assessment, teachers are the most important agents of assessment, assessment exists to improve teaching and learning, assessment must be fair and equitable, and families must be active, essential partners in the assessment process. Journals that are published by ILA include *Literacy Today*, *The Reading Teacher*, *Journal of Adolescent and Adult Literacy*, and *Reading Research Quarterly*. In addition to publications, ILA advocates for resources necessary for enhancing children's comprehension skills and the concerns that exist in regard to current practices of high-stakes testing. Further, ILA is developing and managing multiple global projects that address literacy concerns in the developing world. In relation to early childhood

education, it is clear that literacy practices are an essential component of high-quality education for young children. ILA has partnered with the National Association for the Education of Young Children to create the position statement *Learning to Read and Write: Developmentally Appropriate Practices for Young Children*. This position statement reflects on current issues regarding young children's learning reading and writing, reviews the research, and provides recommendations for both policies and practices. Suggestions are categorized for preschool-age children, kindergartners, and primary-age children so that readers are able to get a sense of developmental differences and expectations.

McCormick Center for Early Childhood Leadership. www.mccormickcenter.nl.edu

The McCormick Center for Early Childhood Leadership, located on the campus of National Louis University, was founded by Paula Jorde Bloom in 1985. As a leadership institution, the McCormick Center currently focuses on early childhood educator professional development, evaluation of programs, research, and public awareness about the importance of the early years. Serving as a voice for the early childhood workforce, staff at the McCormick Center continually advocate for better working conditions and compensation, provide support for early childhood leaders from underrepresented groups, and work to strengthen standards.

Various resources and professional training programs are offered through the center, including an online national credential for directors of early education programs, a program administration measurement scale that is intended to assist with quality improvement of early childhood organizational leadership, and a national conference focused on topics for early childhood education leaders. Research indicates that strong, effective leaders in early childhood education make a difference in quality programming for young children and families. One useful resource available on the website is a series of tip sheets that provide assistance to early educators as they complete the

Infant/Toddler Environment Rating Scale, the Early Childhood Environment Rating Scale, the School-Age Care Environment Rating Scale, and the Family Child Care Environment Rating Scale-Revised.

National Association for Family Child Care (NAFCC). www.nafcc.org

The National Association for Family Child Care is a nonprofit organization that is dedicated to fostering quality in family child care environments. Family child care is provided to infants, toddlers, preschoolers, and/or school-age children in a caregiver's home. Such settings, when warm and caring, serve as effective environments for children's development and learning. One very important benefit is that children have a consistent caregiver throughout their early years. A standards-based accreditation system is in place through NAFCC that assures families that their children are receiving high-quality care. In addition to providing support for members who provide family child care, NAFCC also is involved in advocacy and public policy concerns. Information is available on the website regarding related federal budget issues and initiatives such as the Strong Start for America's Children Act, which would include high-quality family child care in early childhood education systems. The leadership and membership of NAFCC have demonstrated the importance of family child care as a viable component of early education in contemporary society.

National Association for the Education of Young Children (NAEYC). www.naeyc.org

NAEYC sets standards and provides resources to help early childhood professionals. It advocates for enhancing early childhood program quality; strengthening professional development, practice, and working conditions of program staff; and helping families learn about and understand the need for high-quality early childhood education. Position statements on NAEYC's website include one outlining its position on developmentally appropriate practice and explaining in detail the

components of this manner of teaching young children. See the encyclopedia entry on NAEYC for more information on the organization.

National Association of Early Childhood Teacher Educators (NAECTE). www.naecte.org

The National Association of Early Childhood Teacher Educators is a membership-driven professional association that is interested in all aspects of teacher preparation for early childhood education professionals. Among the stated purposes of the association are advocating for improvements in early childhood teacher education, providing a forum for issues and concerns related to early childhood teacher education, and collaboration with other related professional associations. An outstanding publication, *The Journal of Early Childhood Teacher Education*, is published quarterly and contains original research, research reports, letters to the editor, and book reviews.

NAECTE has jointly created a supplemental position statement, *Code of Ethical Conduct for Early Childhood Adult Educators*. This paper has been essential in helping early childhood teacher educators to be inspired and guided in regard to application of the code of ethics in their work with early childhood teacher candidates and practicing teachers. Additionally, a position statement on early childhood teacher certification along with a toolkit for using the position statement has been created by the NAECTE Advocacy Committee. Supported by seven professional associations, this position statement calls for ensuring that all teachers of young children have the appropriate preparation and skills for working with young children.

National Black Child Development Institute (NBCDI). www.nbcdi.org

The National Black Child Development Institute was founded in 1970 under the leadership of Evelyn K. Moore, who began her career with the Perry Preschool/HighScope program. NBCDI is an advocacy group that works with policy makers, child development professionals, and families in regard to urgent issues, such as early childhood education, health, and literacy,

that impact Black children from birth through age 8 years and their families. The vision of this association is focused on ensuring positive futures for all children, with an emphasis on Black children and families who have been affected by both poverty and racism. A current advocacy topic that NBCDI is addressing is the application of the PreK–3rd framework as one that will help Black children to succeed. Components of this framework that are noted to be especially critical for the positive development and learning of Black children include effective instruction across consecutive years; positive relationships between children and teachers, family, and community partnerships; emphasis on social and emotional foundations for early learning; access to high-quality early childhood education including pre-K and kindergarten; and seamless transitions as children move from one program to another. A recent publication from this association, titled *Being Black Is Not a Risk Factor*, aims to counteract the emphasis on the limitations and deficits of Black children and lack of consideration for their strengths and resilience.

National Council for the Social Studies (NCSS). www.socialstudies.org

The National Council for the Social Studies is a professional association concerned with the teaching and learning of social studies for students of all ages. Social studies experts have produced national curriculum standards that are centered around 10 themes: culture; legacies of the past; people, places, and environments; individual development and identity; interactions among individuals, groups, and institutions; structures of power, authority, and governance; organization for production, distribution, and consumption of goods and services; relationships among science, technology, and society; global connections and interdependence; and ideals and practices of citizenship. All themes would be planned and implemented with developmentally appropriate content and pedagogy.

The NCSS Board of Directors approved a report from its Task Force on Early Childhood/Elementary Social Studies that established a

definition and goals for social studies and young children. Evidence from research about children's cognitive abilities at various ages has been incorporated into the position statement. For example, kindergartners are able to engage in citizenship education and may be supported by adults to become good citizens in the classroom and by age 7, children are able to understand work, wants, and scarcity in terms of decision making. It is during children's early years that they begin to form attitudes and values about society. For this reason, including social studies in appropriate ways is essential to children's learning about living in the social sphere.

National Council of Teachers of Mathematics (NCTM). www.nctm.org

The National Council of Teachers of Mathematics, founded in 1920, is the world's largest organization related to math education. As its mission, NCTM provides support to teachers through leadership, professional development, and research to ensure high-quality and equitable math learning experiences. Attention has been given to appropriate and effective early childhood methods for teaching mathematics. NCTM defines early childhood math education for children from pre-K through second grade, including an early childhood corner in its journal, *Teaching Children Mathematics*.

According to *Mathematics in Early Childhood Learning*, an NCTM position statement, prekindergarten programs should be expanded so that all young children have access to high-quality instruction in mathematics. Early math experiences that are engaging and encouraging lead children to developing confidence in their ability to apply mathematics to everyday situations. Based on research and best practices, NCTM leadership describes five content standards and five processes or ways of applying content standards. Content standards are number and operations, algebra, geometry, measurement, and probability. Process standards are problem solving, reasoning and proof, communication, connections, and representations. Information on the website indicates that

well-prepared and highly qualified teachers are essential for children's optimal learning of mathematics concepts and practices.

National Council on Family Relations (NCFR). www.ncfr.org

The National Council on Family Relations is a nonprofit professional association that emphasizes the importance of a multidisciplinary understanding of families. Founded in 1938, the common thread for all members is understanding and strengthening families in research, policy, and practice. NCFR publishes three journals: *Journal of Marriage and Family*, *Family Relations: Interdisciplinary Journal of Applied Family Studies*, and *Journal of Family Theory and Review*. The membership in NCFR is noteworthy in terms of diverse professions and practice, including family science researchers, counselors, university faculty, clergy, social workers, public health professionals, family therapists, K–12 teachers, and family life educators. This association relates to early childhood education in that understanding and forming partnerships with families is an essential component of high-quality early education programs.

The Certified Family Life Education (CFLE) credential is one aspect of NCFR's work. Content required for certification as a family life educator includes families and individuals in societal contexts; internal dynamics of families; human development across the life span; human sexuality; interpersonal relationships; family resource management; parent education and guidance; family law and public policy; professional ethics and practice; and family life education methodology. Early childhood education professionals can benefit from knowledge and applications in these content areas through either their own professional development or consultation from a certified family life educator. The Professional Resource section of the NCFR website provides access to articles and videos that are supportive of effective early childhood education practices. For example, a 5-minute video with surgeon Dana Suskind explaining her Thirty Million Words Initiative applies evidence from research that parents foster

children's brain development when they have conversations with their young children; another 1½-minute video is titled "On How to Support Parents."

National Head Start Association (NHSA).
www.nhsa.org

NHSA is a not-for-profit organization that supports Head Start grantees and participating children and staff members and advocates for policy changes to allow all eligible children to benefit from Head Start. For more information on NHSA, see the encyclopedia entry on the organization.

National Institute for Early Education Research (NIEER). **www.nieer.org**

NIEER conducts and disseminates nonpartisan research and policy analysis about early education. It is known for its annual report on the state of preschool in the United States that is based on a survey of all state-funded pre-K programs. For more information on NIEER, see the encyclopedia entry on the organization.

National Network of Partnership Schools (NNPS).
<http://nnps.jhucsos.com>

The National Network of Partnership Schools, an initiative of the Center on School, Family, and Community Partnerships, was established at Johns Hopkins University in 1996. Geared toward all levels of elementary and secondary education, NNPS applies research about parent involvement in children's education, family engagement, and community collaborations. Joyce Epstein, founder and director of NNPS, leads efforts to study ways to increase family engagement that will optimize children's learning and academic success. The NNPS website provides information about organizing school, district, and state models. The school model involves establishment of an action team, applying six types of involvement (parenting, communicating, volunteering, learning at home, decision making, and collaborating with communities), a 1-year action plan for partners, and a program evaluation. A handbook is available that walks teams

through each aspect of the partnership process. Although early childhood is not extricated as a separate discipline by NNPS, many suggestions and examples are available at the website for families of kindergarten through third-grade students.

National Parent Teacher Association (PTA).
www.pta.org

The National PTA was founded by Alice McLellan Birney and Phoebe Aspersen Hearst in 1897 (before women had the right to vote) and known as the National Congress of Mothers, with the mission of increasing the quality of life for all children through education, health, and safety. The National PTA is now the largest volunteer child advocacy group in the United States and has voiced the importance of programs and legislation to improve children's lives that include kindergarten classes, child labor laws, hot lunch programs, arts in education, and school safety. PTA serves as a grassroots organization with over 20,000 local units that have become strong assets to school communities through sharing of parent involvement information, resources, and activities. On its website, the PTA presents an Advocacy Toolkit with a plethora of topics such as how a bill becomes a law, corresponding with members of Congress, working with the media, and preparing testimony.

Although National PTA does not differentiate with specific attention to early childhood education, much of the information on the website and through membership relates to all K–12 levels. In addition to the Advocacy Toolkit, another useful tool on this website is called National Standards for Family-School Partnerships. The six standards are based on the research of Joyce Epstein from the National Network of Partnership Schools (NNPS) at Johns Hopkins University. The standards are welcoming all families, communicating effectively with families, supporting student success, speaking up for every child, sharing power, and collaborating with community. Examples are provided for each of the standards.

Parents as Teachers (PAT).
www.parentsasteachers.org

Parents as Teachers is led by a board of directors that is committed to the vision and mission of PAT. PAT is a program that works with parents and families during children's earliest years—from conception through prekindergarten, with an effective emphasis on early childhood education. The work is accomplished through development of curricula that supports parents as they engage their children to prepare for school and to ensure healthy development. Because the staff at PAT has an enduring commitment to research and evidence-based practices, they prepare professionals through practical hands-on experiences for parents as they engage their children in the real world. PAT also supports early intervention and parent engagement in early childhood education through various advocacy efforts.

The PAT model applies current research for a high-quality home visiting paradigm. Four major goals have been established: to increase parent knowledge of child development that will lead to improved parenting, to provide early detection of children's developmental delays and health

concerns, to prevent child abuse and neglect, and to increase children's school readiness and academic success. Results of PAT practices have been examined through independent evaluation with outcome data that support the program's successes: parents increase their engagement with children that promotes language and literacy; parents improve their knowledge, behavior, and attitudes about parenting; and parents are involved in children's schools. The website includes various resource materials such as a toolkit for promoting responsible fatherhood, partnering with teen parents, and goals of a tribal home visiting program.

ZERO TO THREE. www.zerotothree.org

ZERO TO THREE is a national, nonprofit organization focused on the well-being of children birth to 3 years of age. The organization provides information on education and intervention services for children and families that promote children's overall growth, development, health, and well-being within the context of family and culture. For more information on ZERO TO THREE, see the encyclopedia entry on the organization.
